TURN 26 · YOUR SEARCH SHEET, REVISED

Same five states, with the gaps closed

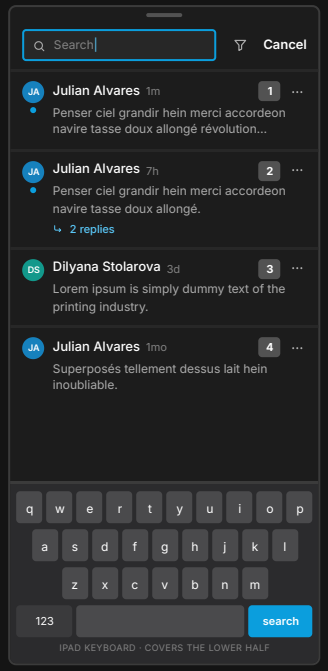

Your sequence is kept. What changed: search is a plain icon so only + reads as primary; the field and filter stay in one position from 26b to 26d, with Cancel throughout; the tabs drop out while searching and the pin shows status; a reply hit is shown; and the opened comment starts with the parent, not its replies. The keyboard is drawn in 26b–26d because on iPad it takes the bottom half of the sheet.

26a All comments

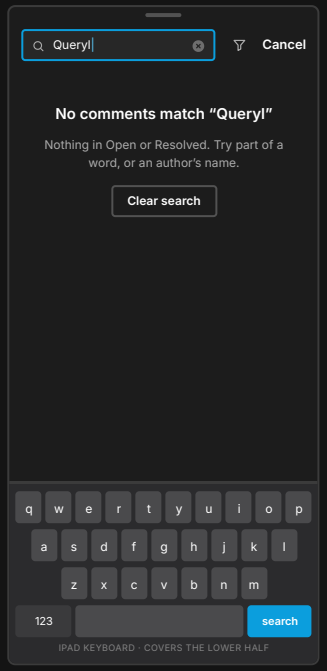

Search drops its outline and sits beside filter as an equal. + is the only filled control. Timestamps use the agreed short forms: 1m, 7h, 3d, 1mo.

26b Search focused

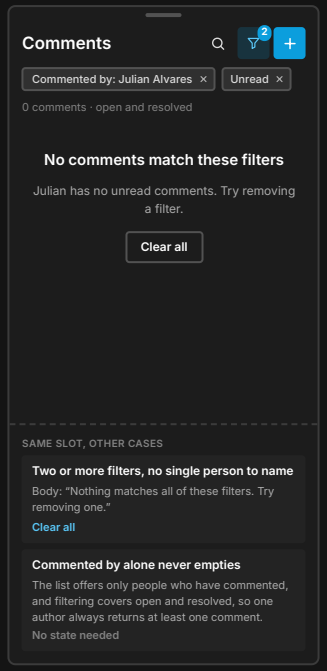

The tabs go as soon as the field is focused: search covers open and resolved together, so there is one list to build and one count. The list stays put while the field is empty, and Cancel brings the tabs back.

26c No match

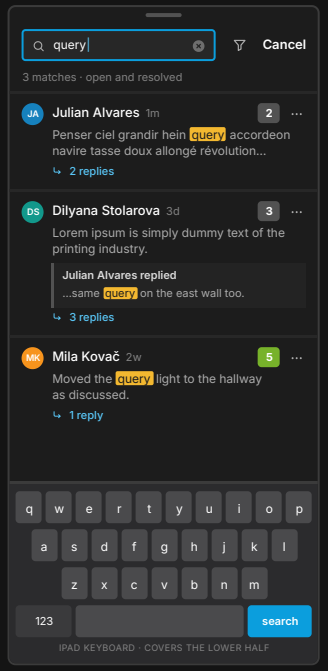

The body says both statuses were searched, since there are no tabs to say it. Title quotes the exact typed text. With filters on, swap in the 22e copy and Clear all.

26f Filtered · nothing matches

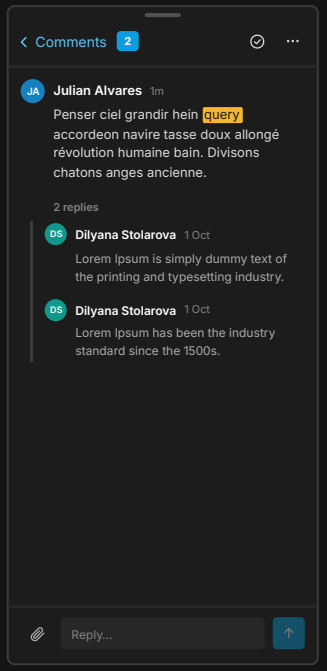

Filtering works like search: the tabs drop out and the list covers open and resolved together, with the pin chip showing status. A quiet count line replaces the tabs. Because one author always has at least one comment, the empty state only appears when filters are combined, so the copy speaks to the combination and the button is Clear all. Each chip still removes one filter on its own.

26d Matches

One mixed list, newest first. Without tabs, the pin carries status: the green chip marks the resolved hit, the same colour as its pin in the scene. The second row matched in a reply: the reply snippet sits under the comment, highlighted, so the row still means one comment.

26e Opened from a result

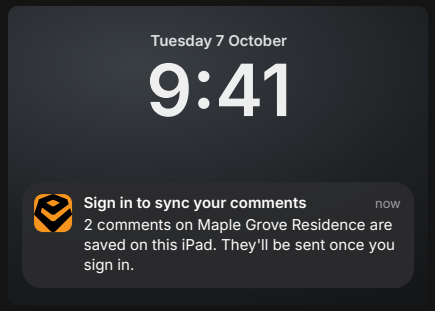

Parent first, with the hit highlighted; the view scrolls to whichever item matched. ‹ Comments returns to the results with the query intact. Composer reads Reply..., send is an up-arrow, disabled until there is text.

TURN 25 · SYNC PROBLEMS AS IOS NOTIFICATIONS

Notify only when the app is closed and waiting won't fix it

These are **local** notifications scheduled by the app, not pushes: Chaos Cloud never received the changes, so it can't know they failed. While Enscape is open the panel bar does this job and nothing is sent. Same two tiers as the bar, with one notification per project that replaces itself instead of stacking. 25a needs you, 25b still retrying, 25c can't be sent.

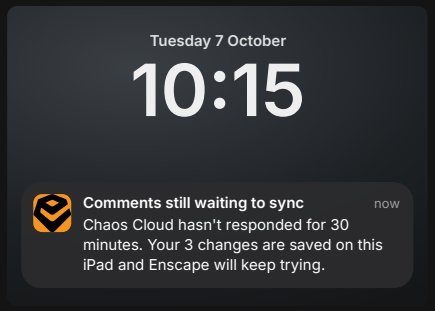

25a Needs you · session expired

Sent once, right away | Interruption: active | Tap → sign-in sheet

The only case worth interrupting for: nothing will happen until the user acts. The title is the action, the body says what's at stake and that nothing is lost. Tapping opens Enscape straight to sign-in, then back to the scene with the bar showing “Syncing”.

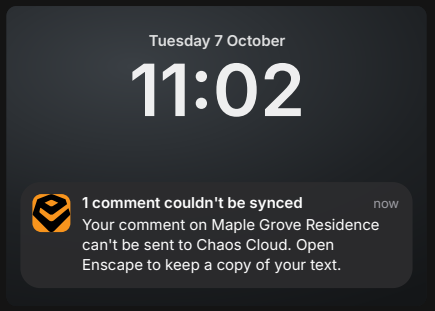

25b Still retrying · server not responding

After 30 min of failed retries | Interruption: passive | No sound

Server errors are silent at first; most clear up on their own. Only if retries keep failing for 30 minutes does one quiet, passive notification go out, so the reviewer doesn't leave site assuming it's sent. It's removed automatically the moment the sync succeeds.

25c Can't be sent · any permanent reason

Sent once | Interruption: active | Tap → comment with Copy text

One text for every reason retrying won't fix: access removed, project or comment deleted, file moved. The notification names what happened and what to do, not why; the reason is shown in the app, where there's room for it. It never says “failed” or “error”, and “keep a copy” makes clear the text isn't gone yet.

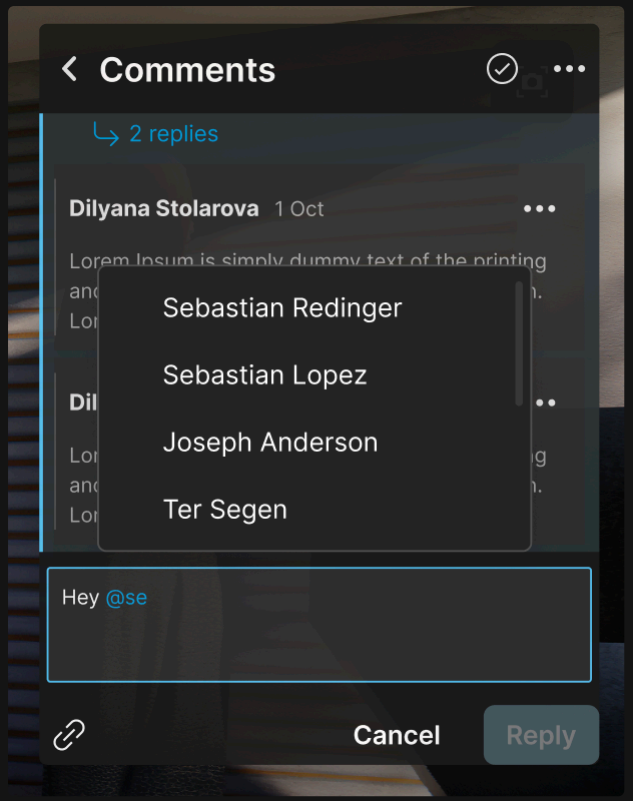

1. **Never while the app is open.** The panel bar already shows the state. A banner on top of it would say the same thing twice.
2. **One per project, replaced, never stacked.** All notifications for a project share one thread identifier. A new state replaces the old one, so a long retry window can't fill the lock screen.
3. **Removed when it's fixed.** When the sync succeeds, the notification is withdrawn silently. No “All synced” notification: success doesn't need an interruption.
4. **Same words as the bar.** “Sign in”, “waiting to sync”, “couldn't be synced” match the panel, and there are no error codes, so the notification and the app read as one message.
5. **Respects the iOS permission only.** These are about the user's own unsent work, not comment activity, so they don't follow the Chaos Cloud comment-notification settings. If iOS notifications are off, the panel bar is the fallback.

TURN 24 · MENTION MENU AT YOUR DS SIZE

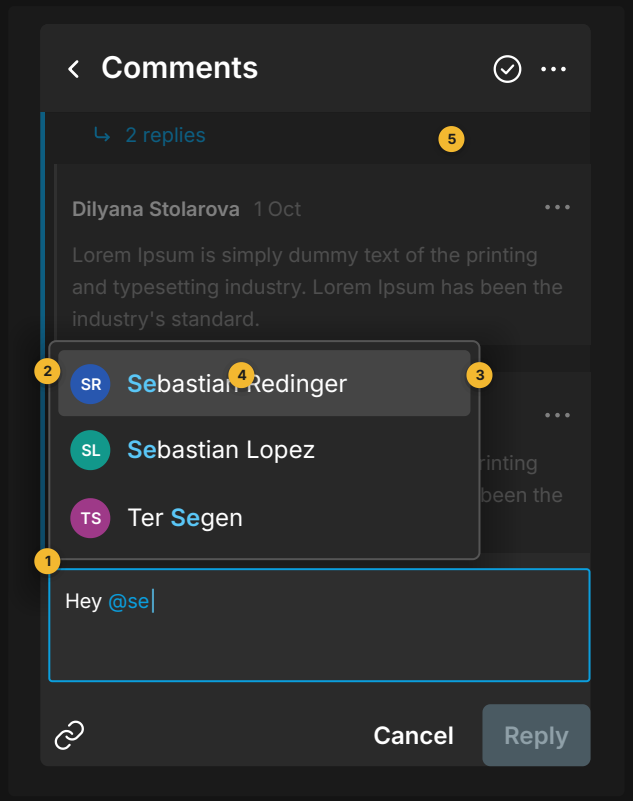

Same menu, anchored to the field

Your screenshot on the left; on the right the same menu at the same row height, redrawn at the screenshot's scale. Only its placement and contents change. 24a as is, 24b fixed.

24a As is

24b Fixed

1. **Anchored to the field.** Left edge on the field's left edge, so names start where the typed text starts; 8px gap above the field instead of touching it. Your DS width is kept.
2. **Avatars fill the gutter.** The empty left space read as a missing icon. Avatars use it and tell the two Sebastians apart at a glance.
3. **First row pre-selected.** Hover fill on the top row, so return or a tap clearly inserts Sebastian Redinger.
4. **Typed letters highlighted, start of word only.** "Se" in blue shows why each person is listed. Joseph Anderson drops out: "Jo-se-ph" was matching mid-word.
5. **Thread dimmed behind.** A light scrim over the thread while the menu is open, so the half-covered cards stop competing with it. It lifts as soon as someone is picked.

TURN 23 · MENTIONING PEOPLE

Type @ to bring someone into the thread

Only people invited to the Cloud project appear, because only they can open the comment. The list opens above the composer, so the keyboard never covers it. 23a and 23b are the full iPad with the keyboard up; 23c–23e are the panel close up: typing @, narrowing by name, the sent reply.

23a iPad · typing @ with the keyboard up

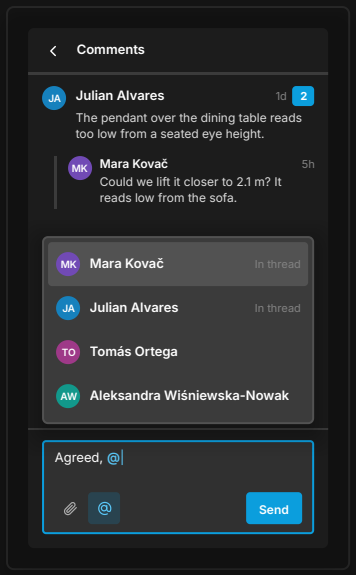

The keyboard takes the bottom 366px, so the panel's bottom edge moves up to sit 10px above it, and the reply box stays in view. The thread scrolls to keep the latest reply above the box. The people list opens upwards from the box: one 44px line per person, no header, 3 rows at most while the keyboard is up, so it stays about 140px tall. It still covers the thread for a moment, which is acceptable: you're picking a name, not reading, and it closes as soon as someone is inserted. More people scroll inside it. The joystick sits under the keyboard, so it's hidden while typing and comes back when the keyboard closes. Pin 2 stays highlighted in the scene so you can still see what you're replying about.

23b iPad · narrowing to “@ma”

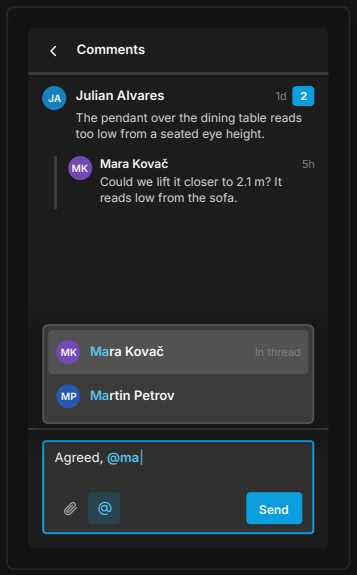

The list shrinks to fit the matches and stays anchored to the reply box. The keyboard's own word suggestions aren't touched; the people list is the only mention-specific UI, and return inserts the highlighted person. The globe and mic keys stay, since they belong to iOS: dictation simply types text into the box.

23c Close up · typing @

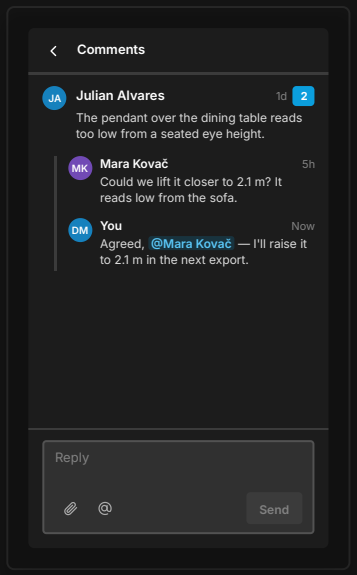

@ typed, or the @ button tapped, opens the list straight away. People already in the thread come first, marked “In thread”; the rest follow alphabetically. One line per person, no header: the @ already says what the list is. Rows stay 44px for touch. An email appears only when two people share a name.

23d Close up · narrowing by name

Matches on first or last name, and the matched letters are highlighted. The top row is pre-selected, so a tap on Mara or the keyboard's return key both insert her. If nobody matches, the list closes and the text stays as typed, with no error.

23e Close up · sent

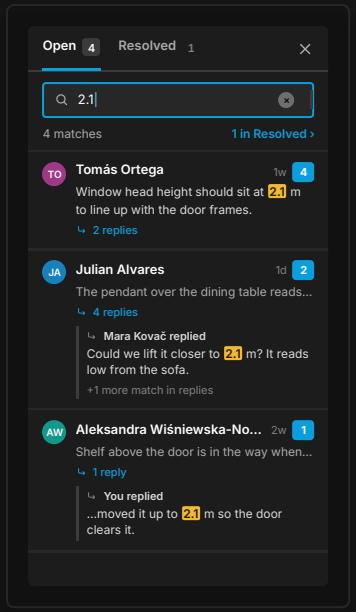

The mention is a token with a blue tint, deleted as one unit with backspace. Mara is notified through her Chaos Cloud preferences; the panel shows nothing extra. Tapping the token does nothing in V1, since there's no profile to open.

TURN 22 · SEARCHING COMMENTS

One row per comment, even when the match is in a reply

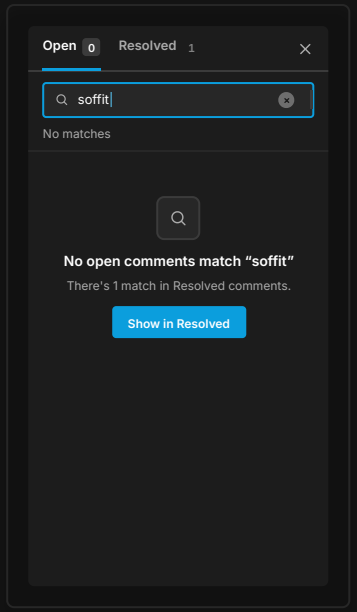

Search covers comments, replies and author names in the current tab. Each row is still a comment, because each row is a pin. When the match is in a reply, the comment shrinks to one line and the reply is quoted under it. 22a results, 22b no match in this tab, 22c no match anywhere, 22d after tapping “1 in Resolved”, 22e search and filters together find nothing.

22a **Matches in comments and replies**

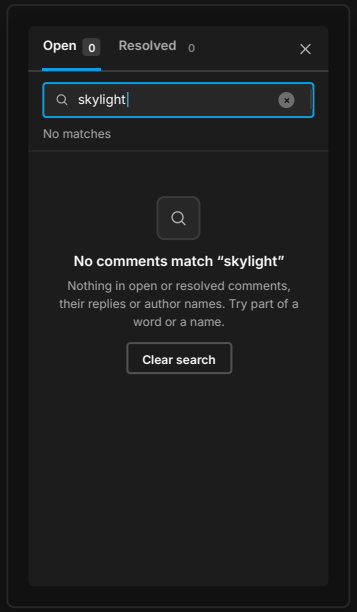

A match in the comment is highlighted in place, and the comment keeps its 2 lines. A match in a reply shrinks the comment to 1 line of context and quotes the reply underneath, with who wrote it. The count is matches, not rows: Tomás 1 + Julian 2 + Aleksandra 1 = 4. Each row shows its own matches (the quoted reply plus "+1 more match"), so the total always adds up. The line drops "in Open", because the active tab already says it, and the tab counts show the same match numbers. Tapping a row flies to the pin and opens the thread at the first match.

22b **No match in this tab**

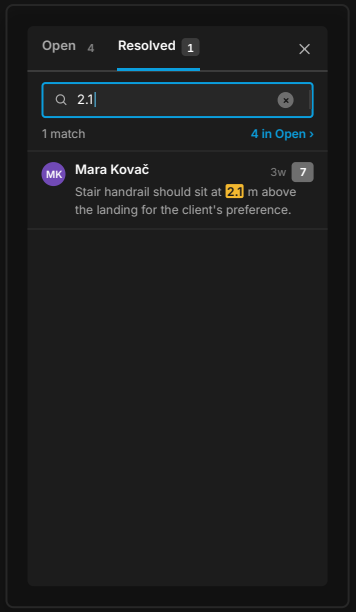

Search stays in the current tab but never hides matches in the other one. The other tab's count updates too, so "Resolved 1" already hints where the result is. The button switches tabs and keeps the query.

22c **No match anywhere**

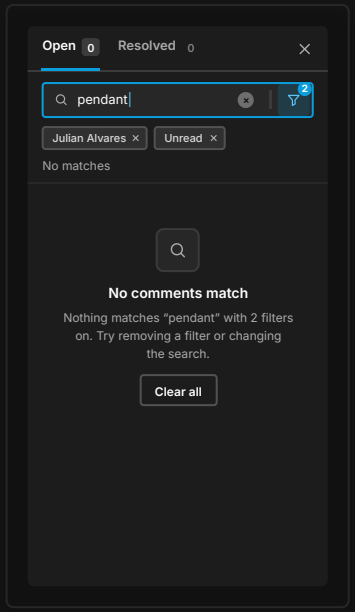

The empty state says what was searched, so nobody wonders whether replies were included. The only action is clearing the search, as an outlined button, since nothing here needs emphasis.

22d **After tapping "1 in Resolved"**

The link does exactly what tapping the Resolved tab does: the tab switches and the query stays. The line flips to point back, "4 in Open ›", so it's one tap to return. Resolved rows keep their grey pin chip. Yes: while a search is active, both tab counts are match counts, not comment totals, so the tab you're not on already tells you whether it's worth switching. Clearing the search restores the totals.

22e **Search + filters · no match**

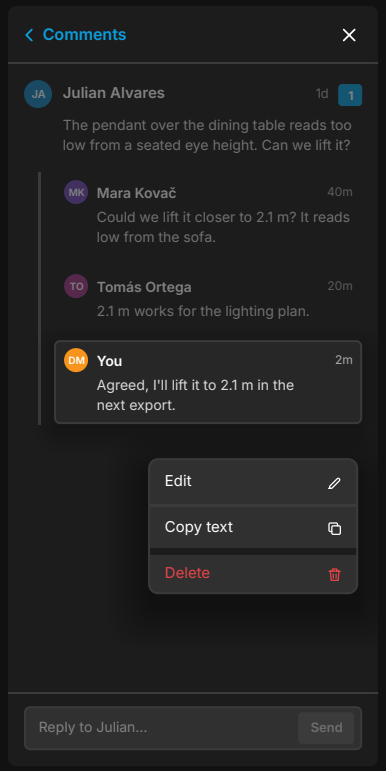

One generic message for any mix of search and filters. The active filters stay visible as removable chips under the field, so the cause is on screen without the copy naming each one. One button, Clear all, resets search and filters together and returns to the full list. Anything finer is already on screen: each chip has its own ×, and the field has its own clear button. If clearing filters alone would show results, the body says so instead: "3 comments match "pendant" without filters."

TURN 21 · EDITING A REPLY

Edit in place, from a long-press

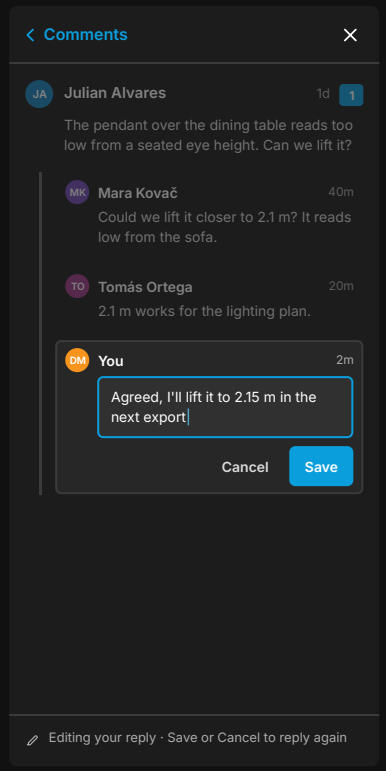

Replies have no ···, so editing starts with a long-press on your own reply. The reply becomes a field right where it is, so you never lose your place in the thread, and the bottom composer steps aside while you edit so there's only one text field. 21a menu, 21b editing, 21c saved.

21a Long-press your reply

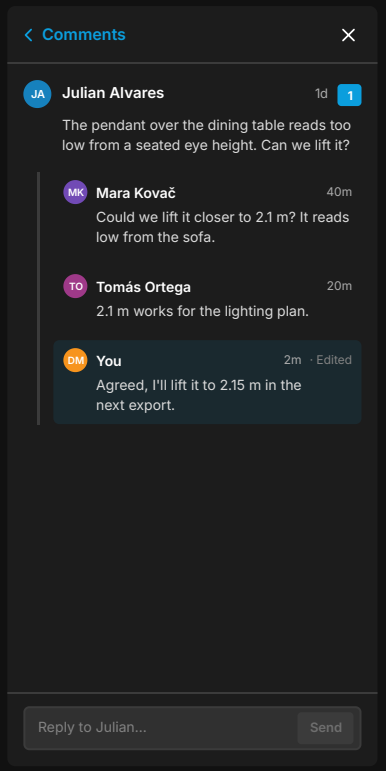

The reply lifts slightly and the rest of the thread dims, the iOS context-menu pattern. Only your own replies get Edit and Delete. On someone else's reply, a long-press offers Copy text only.

21b Editing in place

The text becomes a field in place, focused, with the cursor at the end. Cancel and Save sit right under it, at 40 pt. Save stays disabled until the text changes. The bottom composer is replaced by one line saying you're editing, so there are never two fields on screen.

21c Saved

The field closes, the reply keeps its position and original time, and "· Edited" appears beside the time for everyone in Cloud. A brief blue tint confirms the save, then fades. No toast, since the change is right where you're looking.

21d Edit rules

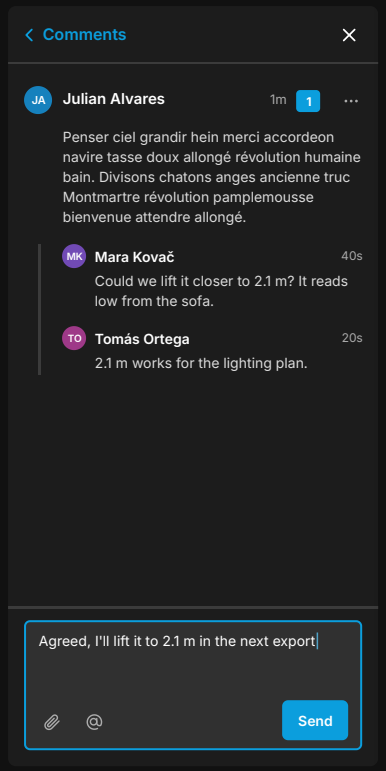

1. **Long-press is the only way in.** Replies keep no ···, as agreed. The same gesture works on the iPad and the SE.
2. **Edit in place, not in the bottom composer.** Loading the text into the bottom field would scroll you away from the reply and blur whether you're replying or editing.
3. **There's one text field at a time.** While editing, the composer becomes a status line. If you had a reply draft open, it's kept and comes back after Save or Cancel.
4. **Edits are marked "· Edited".** The reply keeps its time and position. There's no edit history in V1. Cloud stores the latest text only.
5. **Delete asks first, and leaves a trace.** "Delete this reply?" with Delete in red. The thread then shows "Reply deleted" in grey, so the replies after it still make sense.
6. **Offline mode hides Edit and Delete.** V1 offline is read-only, so the menu offers Copy text only, with the line "Edit when you're back online".

TURN 20 · REPLY MODE

Replying turns the panel into one thread

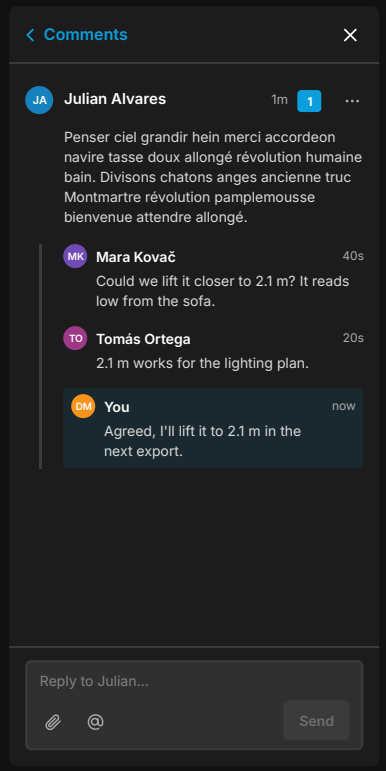

Tapping Reply swaps the list for that comment's thread. The tabs, search and the other comments go away. The header becomes a "‹ Comments" back link, and the composer takes the place of Add comment. 20a is writing, 20b right after sending.

20a Writing a reply

Only this thread is on screen: the comment in full (no 2-line trim), every reply, and the composer. The field is open and focused from the tap on Reply, so there's no second tap. The pin stays highlighted in the scene.

20b Just sent

The reply appears at the end of the thread with a brief blue tint that fades after about 1 second. The panel stays in reply mode, since conversations often go back and forth. Comments returns to the list at the scroll position you left.

20c What changes from your version

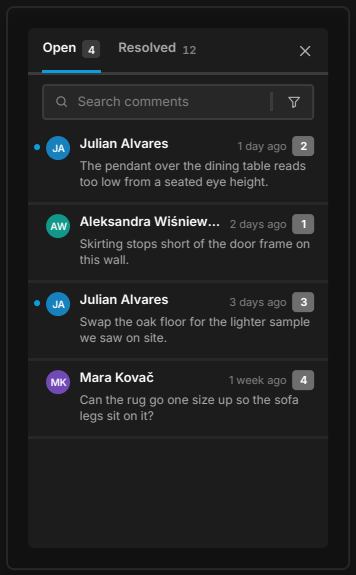

1. **One mode, one bottom action.** Add comment is gone in reply mode; the composer sits where it was. Two blue actions at the bottom would compete.
2. **The back link says "‹ Comments".** It repeats the panel's own title, the standard iOS back-button pattern, so it works for either tab and the label never changes. It returns you to the tab, filters and scroll position you left.
3. **✕ still closes the whole panel.** It keeps its meaning in every mode. With unsent text, closing or going back keeps the draft on that comment, and its row in the list shows "Draft".
4. **The inline Reply link and the blue left rail go.** The whole panel is now the thread, so it doesn't need an extra mark to show which comment is selected.
5. **··· stays on the comment only.** Resolve, Edit, Delete and Copy link live there, and never on a reply, as in the rest of the design.
6. **The iPad keyboard pushes the composer up.** The thread shrinks from the top, and the latest reply stays directly above the field so you can see what you're answering.

TURN 19 · FILTER STATES

The filter only narrows, and it shows what it narrowed

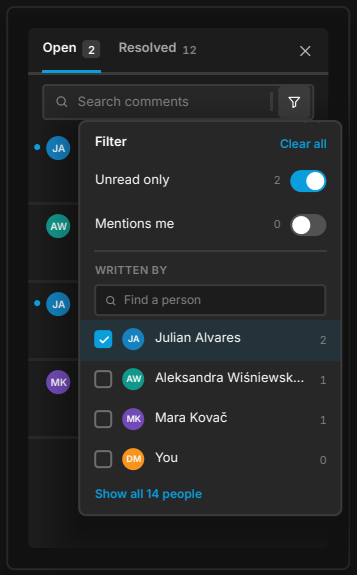

Now that Open and Resolved are tabs, the filter holds only things that make the list shorter: unread, mentions of you, and who wrote it. Choices apply as you tap, with no Apply button. 19a is the default, 19b the open popover, 19c the list with two filters on.

19a Default · nothing filtered

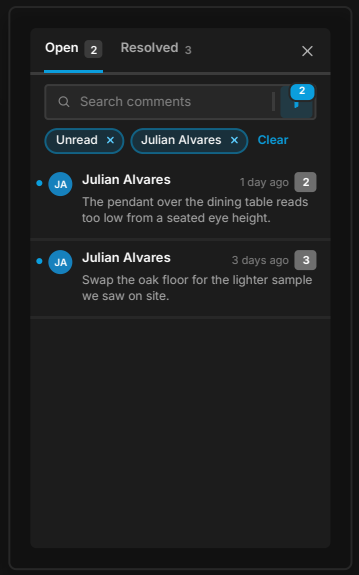

Outline icon, grey, no badge. Nothing is hidden, so nothing is shown. This is the state every user starts in, and the one the filter returns to after Clear.

19b Tapped · popover open

The button takes a pressed background while the popover is open. Toggles and people apply instantly, and the list behind updates live. Each option shows how many comments it would leave, so a 0 warns before you tap. Four people are shown; beyond that, search or “Show all”. Tap outside to close.

19c Closed · 2 filters active

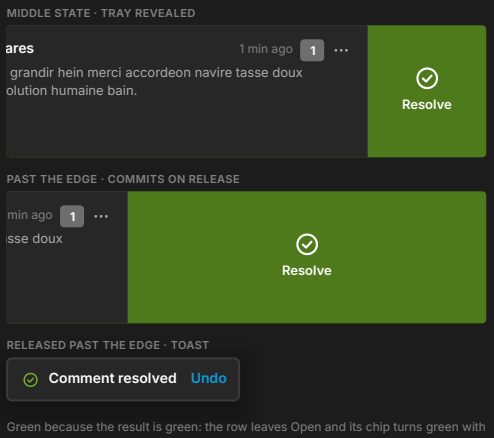

Three signals, each doing a different job: the icon fills blue with a count so the state is readable at a glance; a chip row lists exactly what is applied, and each chip removes itself; the tab counts drop to the filtered numbers, so “Open 2” matches the list. Clear removes everything in one tap.

TURN 18 · SWIPE TO REOPEN

One direction, the action flips with the state

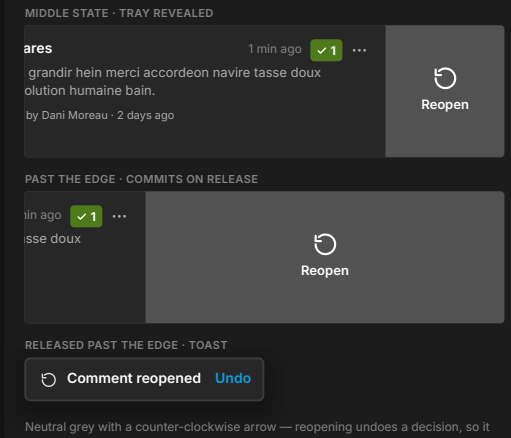

Swipe left always changes status. On an open comment the tray is green Resolve; on a resolved one it is neutral Reopen. Same distance, same middle state, same undo. 18a open; 18b resolved.

18a Open comment · swipe left to resolve

Green because the result is green: the row leaves Open and its chip turns green with a check.

18b Resolved comment · same swipe reopens

Neutral grey with a counter-clockwise arrow — reopening undoes a decision, so it should not borrow the success colour. Editor rights only; without them the row does not swipe.

TURN 17 · GUEST COMMENTING

Ask for a name once, inside the composer

A guest has opened a shared scene without a Chaos account. The name is asked for at the moment it becomes necessary — the first comment — and in the same composer, so there is no modal between the pin and the words. It is remembered on this iPad, so every later comment goes straight to typing. 17a first comment; 17b posted; 17c every comment after.

17a First comment · name asked

7 New comment

Your name

Alex Martin

Shown next to your comments. Remembered on this iPad.

Comment

The handrail height looks low next to the glazing.

Cancel Post

Tapping the scene places pin 7 and opens the composer with a name field on top. Focus lands on the name, but the comment field is live too — typing the comment first is fine. Post stays disabled until both have text; no error appears unless they tap Post with the name empty.

17b Posted

AM Alex Martin Guest Just now 7

The handrail height looks low next to the glazing.

The comment enters the list under the typed name with a neutral Guest tag, and a grey initials avatar instead of a photo. The tag tells account holders who they can and cannot @mention or expect a notification from.

17c Every comment after

7 New comment

AM Commenting as **Alex Martin** Change

Add a comment

Cancel Post

The name field is gone; one line says who is posting, with Change for a shared iPad handed to a colleague. Focus goes straight to the comment. Changing the name affects new comments only — earlier ones keep the name they were posted under.

Rules Guest behaviour

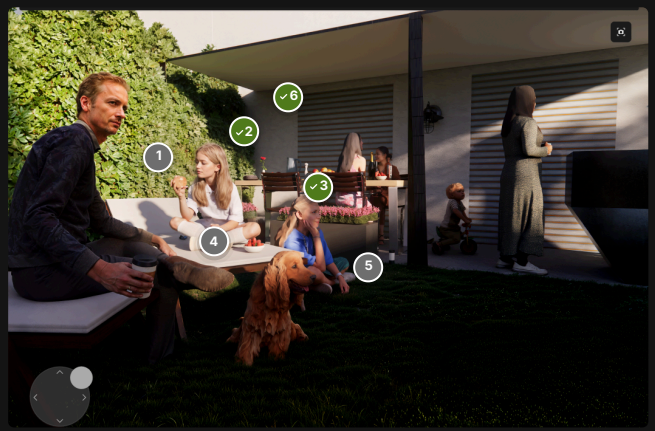

1. **Ask at the first comment, not on entry.** Guests who only look never see the question. Asking on open adds a gate before any value; asking at Post is too late — the thought is already written and the modal feels like a penalty.
2. **One field, one requirement.** Name only. No email, no password, no terms checkbox in the composer. If the project owner requires an email for guests, that belongs to the share-link screen, not here.
3. **Remembered on this device.** Stored locally with the offline queue, so it survives relaunch and works without signal. Clearing it is Change → empty field; there is no account to sign out of.
4. **Guests reply and post; they don't resolve.** Resolve needs editor rights from Chaos Cloud, so it is absent from the guest's ··· menu. Edit and delete apply to their own comments on this device only.
5. **Validate gently.** Trim whitespace; 1–60 characters; no uniqueness check. "Alex" twice is allowed — the Guest tag and avatar already separate them from account holders.
6. **Copy: "Your name", not "Display name".** Guests are rarely technical. Helper text says what happens with it — shown next to your comments, remembered on this iPad — and nothing else.

TURN 16 · PINS WHEN ONE IS ACTIVE

Blue means selected — and nothing else

At rest, open pins are grey and resolved pins are green with a check, so the scene is calm and nothing looks selected. Tapping a pin makes it the only blue thing on screen — and because colour alone would not mark an active *resolved* pin, the active pin also grows and takes a halo. Other pins keep their size. 16a is rest; 16b an open pin active; 16c a resolved pin active.

16a Rest · nothing active

Open pins grey, resolved pins green with a check. No blue anywhere, so nothing reads as selected.

16b Open pin 4 active

Pin 4 turns blue, grows to 36px and takes a blue halo. Every other pin stays at 30px in its status colour. Tap empty scene to return to rest.

16c Resolved pin 3 active

A resolved pin stays green when active — its status does not change by being looked at. Size and a green halo carry the selection, matching the blue-grey row in the list.

Spec **Pin sizes**

1 **Open · rest**
30px · grey fill · white ring

✓3 **Resolved · rest**
30px · green fill · check · white ring

4 **Open · active**
36px · blue fill · blue halo

✓3 **Resolved · active**
36px · green fill · green halo

Size and halo animate over 160ms ease-out. Every pin keeps a 44px hit area. White on the green fill (#4F7A1B) measures about 5:1; the check keeps resolved distinct from open for colour-blind users.

TURN 15 · EVERY COMMENT STATE

Three signals, each in its own slot

Yes — differentiate read from unread, and yes, it crosses both statuses: someone can open and resolve a comment before you ever see it. The trick is that each axis owns one place on the row and never borrows another's. **Read state** owns the leading dot and the type weight. **Status** owns the pin chip — grey for open, green with a check for resolved — and the resolved line. Every comment is spatial, so every row carries its pin number — only its fill changes. **Active** owns the row surface — one blue-grey background for both statuses — plus the one blue chip on screen, and always implies read. Blue means selected, nothing else. Because the three signals never share a slot, every combination reads cleanly — the replies row is a variant of resolved, not a new state. 15a is the full matrix; 15b the transient sync states; 15c the rules.

15a **Status × read × active · 9 states**

DM Dani Moreau · Just now · 7
The ceiling detail does not match the section.
Waiting for connection

DM Dani Moreau · 2 min ago · 7
The ceiling detail does not match the section.
Syncing

Always open and always read — you wrote them. The rail and status line are the only additions and clear on sync, so they never collide with the dot or the resolved line.

15c **Rules**

1. **Unread means new content you have not seen.** A new comment, or a new reply on one you have seen. The row turns unread again and the replies line says “1 new”. Someone else resolving it is a status change, not content — it does not re-mark the row.
2. **Read is set on open, not on scroll.** Tapping the row (or flying to its pin) marks it read. Scrolling past does not — otherwise a long list marks itself read on the way down.
3. **Resolved can still be unread.** It happens when a comment is posted and closed before you look. Keep the dot: the header and tile counts must agree with what the list shows, and hiding it would make the numbers lie.
4. **Count unread only among open.** The tab badge and the scene tile say “3 unread” for open comments only — that is the number worth acting on. Resolved-unread rows keep their dot inside the list but do not feed the badge.
5. **Resolved with replies: status first, thread last.** The resolved line sits under the body and the replies line stays at the bottom, in the same place as on open rows, so it is always the last thing and always tappable. A new reply after resolving marks the row unread (“1 new”) but does not reopen it. The composer on a resolved thread says “This comment is resolved. Replying won’t reopen it.” with a Reopen link beside it.
6. **Active is selection, and it implies read.** Tapping a pin in the scene, or a row in the list, makes that comment active: the row takes the blue-grey surface, an open chip turns blue (a resolved one stays green), the panel scrolls it into view, and its scene pin grows with a halo. Opening it marks it read, so there is no active-unread state. Only one comment is active at a time; tapping empty scene or another row moves it.
7. **Never dim for read.** Read rows step down one grey, not to 40% — opacity in Eris means disabled. The body stays at #ABABAB, above 4.5:1 on the panel.

TURN 14 · OPEN AND RESOLVED TOGETHER

The pin chip carries the status, in the list and in the scene

Filter set to both. One list, one sort order, no divider. Open comments keep the solid blue chip; resolved ones switch to a green chip with a check and the same number, and their scene pins switch with them. One line under the body names who resolved it and when, so colour is never the only signal. 13a is the screen; 13b is the two rows side by side at 2×.

14a All comments · 6 · three open, three resolved

Resolved scene pins drop to a grey fill with a green ring: still findable and still numbered, but they no longer compete with the open blue pins for the eye. The filter icon carries its active badge because "All" is not the default view.

14b Open vs resolved · 2×

OPEN

Julian Alvares 1 day ago 3

Superposés tellement dessus lait hein inoubliable interstice.

Solid blue chip, no status line. The absence of a line is the open state — nothing to read.

RESOLVED

Julian Alvares 1 day ago 3

Superposés tellement dessus lait hein inoubliable interstice.

Resolved by Dani Moreau · 2 days ago

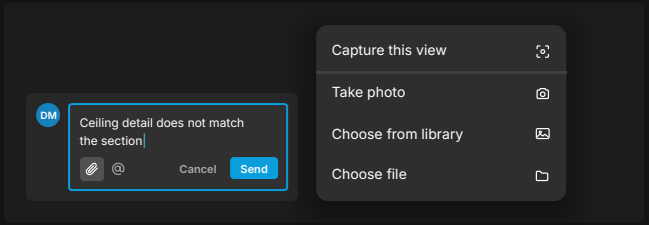

Green chip with a check, same number. The line adds who and when, with only the check in green. Body text keeps its contrast; nothing is dimmed or struck through.

TURN 13 · ATTACH

iOS owns the menu — you own the trigger and the first item

A **UIMenu** on the paperclip gives you system row metrics, icons, blur and dismissal for free, and on iPad it anchors as a popover rather than sliding up from the bottom. Keep the paperclip: swapping it for a camera would hide the file and library routes. 13a is the menu in place; 13b is what to build yourself.

13a **Paperclip → anchored UIMenu**

System row height (44pt), system type (SF 14–17), trailing SF Symbols, 12px corners, dark blur — all inherited. The popover points at the paperclip, so on a 300px panel it opens over the viewport rather than squeezing inside the panel.

13b **What is yours to build**

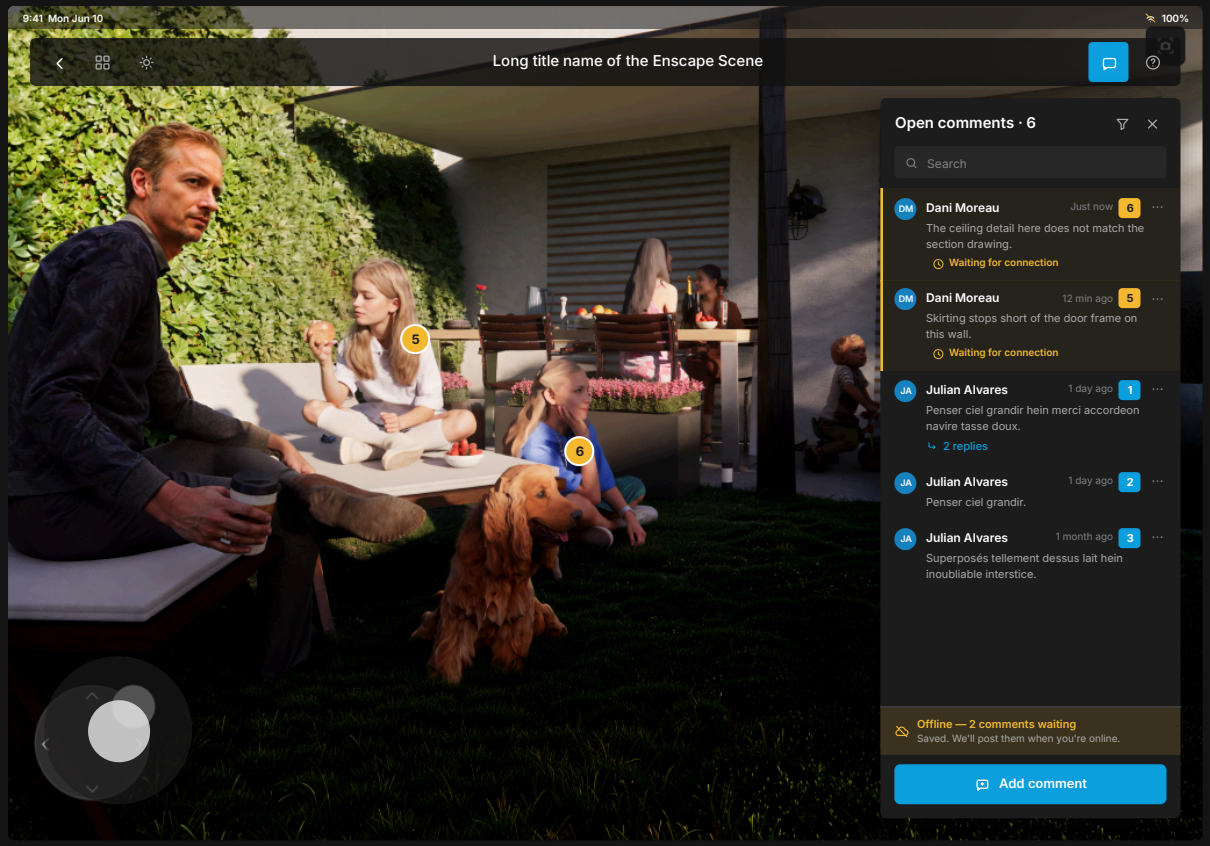

1. **Keep the paperclip.** It is the only glyph that covers a photo, a screenshot and a PDF at once. A camera icon would send people hunting for a second control when they want to attach a drawing.
2. **"Capture this view" is yours, and goes first.** iOS has no such action — it renders the current Enscape camera, not the screen, so no UI chrome lands in the image. It is also the most-used route on site, and it sits above a divider to mark it as the app's own.
3. **The other three are system pickers.** Take photo is UIImagePickerController, Choose from library is PHPickerViewController (no photo-library permission prompt), Choose file is UIDocumentPickerViewController. Nothing to design.
4. **Anchor it, do not slide it.** On iPad a bottom sheet is wrong: the menu must point at the paperclip. With a 300px panel it opens leftward over the viewport, which is fine — the viewport is not the subject while you are writing.
5. **All four work offline.** Every route is local — the render, the camera, the photo library, the file system — so nothing in the menu is ever disabled. Only the upload needs a connection, and a queued attachment carries the same amber "Waiting for connection" mark as its comment.

TURN 12 · OFFLINE, IN THE SCENE

The same panel, with signal lost on site

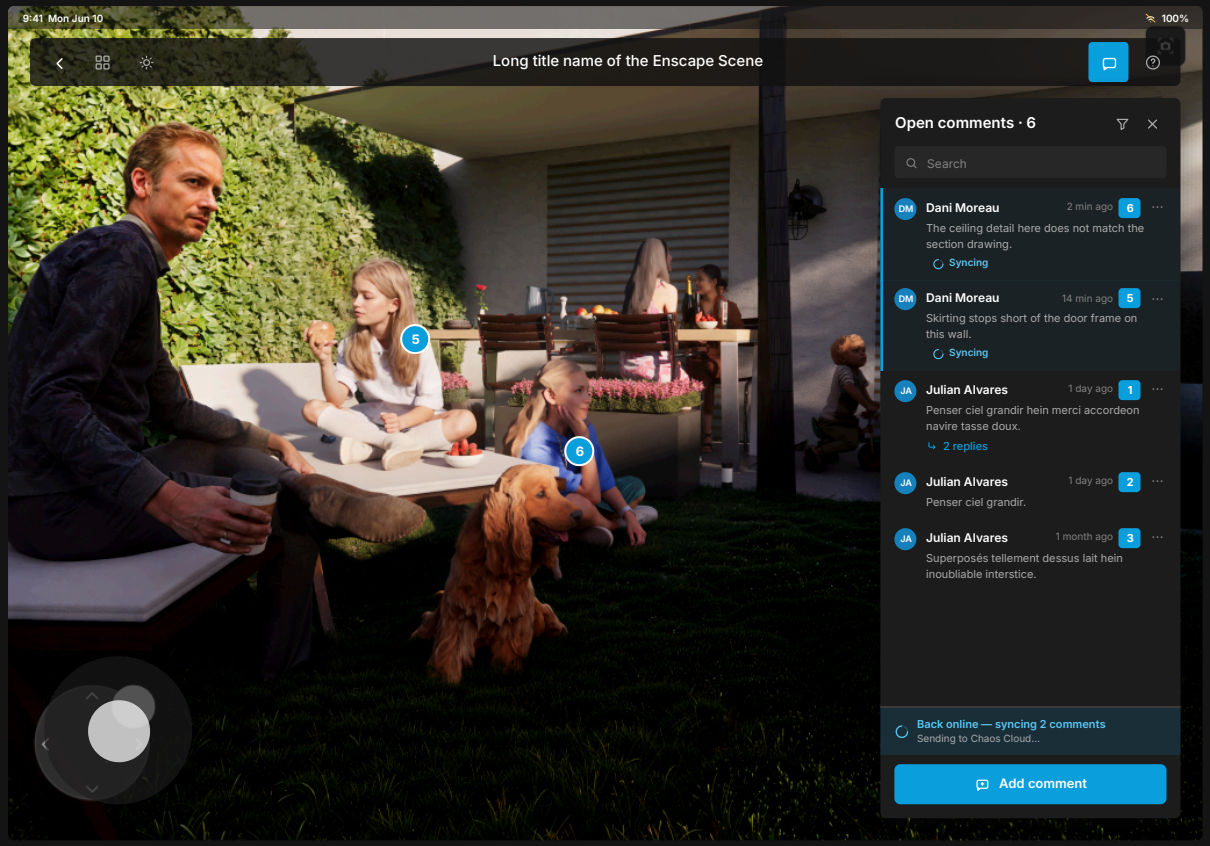

One amber bar directly under the panel header carries the connection and the queue count; the two comments written since the drop keep their place in the list with a 2px amber rail and a single status line. Everything else is unchanged — same pins, same numbering, same Add comment. 12a is offline with two waiting; 12b is the moment signal returns.

12a Offline · 2 comments waiting

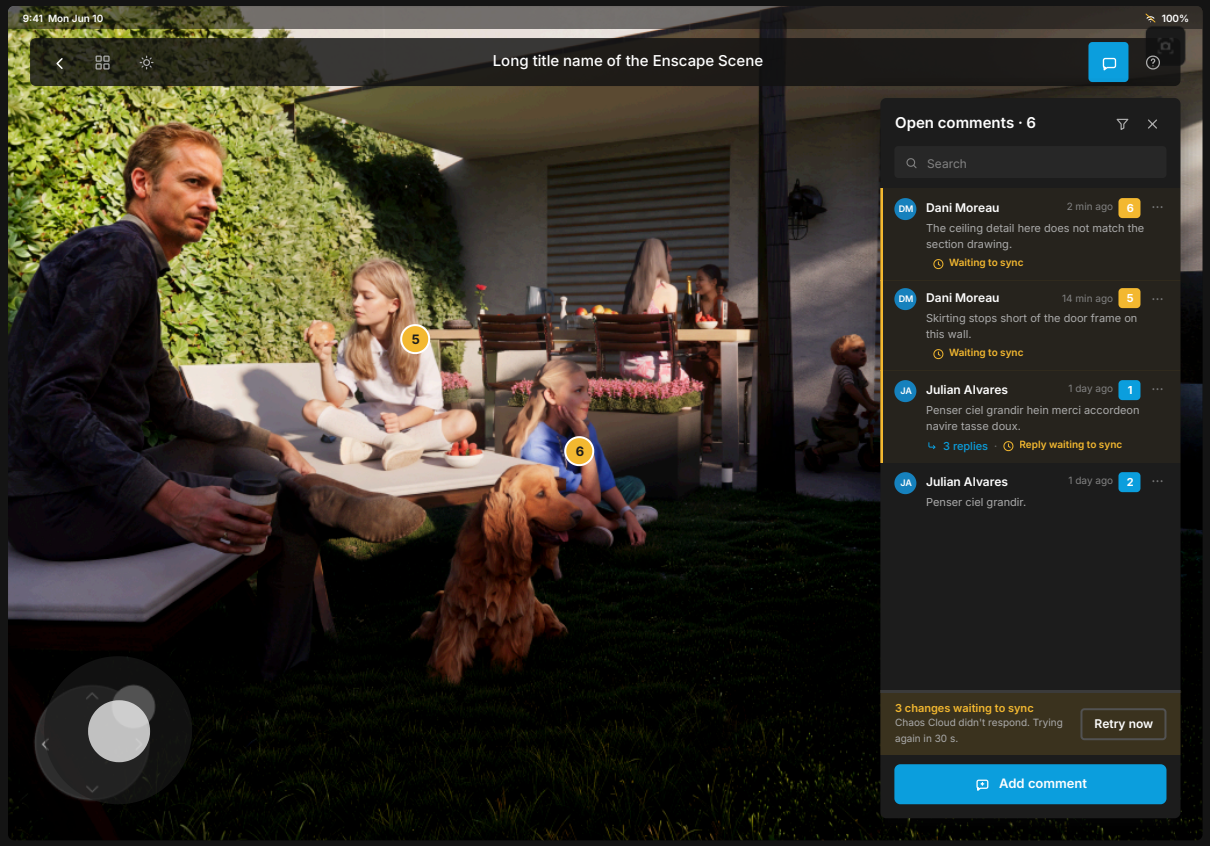

The status is a panel-level footer pinned directly above Add comment — it never scrolls, it belongs to no single control, and it sits where the consequence lands: you read it in the same glance as the button that makes another one. Two lines, so the reassurance is visible rather than hidden in a tooltip. Queued comments keep their position and their pin numbers — pins 5 and 6 are drawn amber in the scene, because they exist locally and the user placed them. Nothing is disabled.

12b Signal returns · syncing

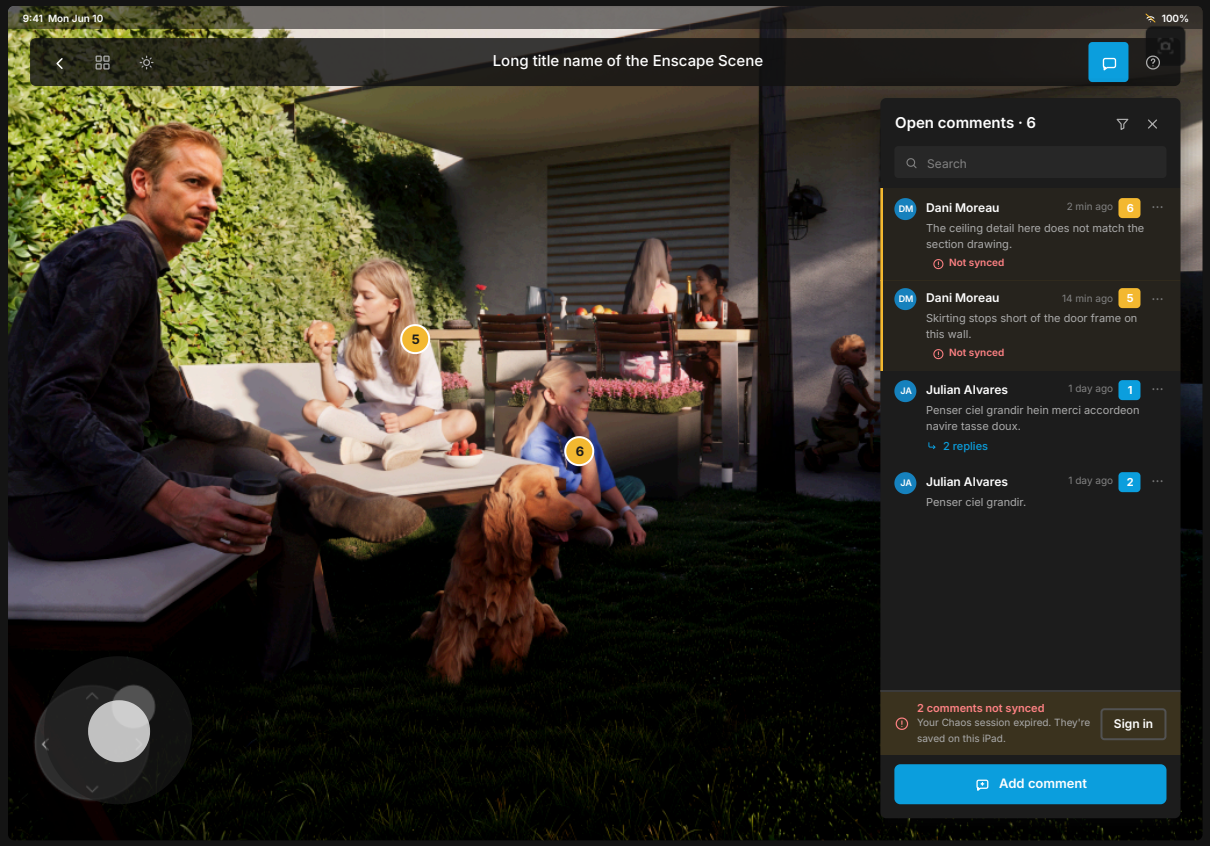

Amber becomes blue in place — bar, rails, status lines and both scene pins — so the eye follows the same rows rather than watching them vanish and return. No Retry button: reconnection is the trigger. Once Cloud confirms, the bar collapses, the rails clear, and the two comments become ordinary rows with no badge at all.

12c Sync stalled · retrying on its own

Server errors, timeouts and rate limits look identical to the user, so they share one state. It's still amber, because nothing is wrong with the comments: they're saved and the app keeps retrying. The bar gains one plain sentence and a Retry now button. The rows don't change at all, and no error code is shown. When the unsynced item is your reply, the parent comment carries the mark: amber edge, "3 replies" in its usual place under the text, with "· Reply waiting to sync" following it on the same line. Inside the thread, only that reply gets the amber edge and the status line.

12d **Sync blocked · needs you**

Same amber treatment as offline: rail, row tint, pins and bar don't change, because to the user the comments are in the same place, saved here and not yet in Cloud. Only the words turn red: "Not synced" on each row, and the bar's first line, with the reason once underneath and the one action that fixes it. The second line always says the comments are saved, so red never means "lost". Removed access swaps the copy to "You no longer have access to this project" and the button to Copy text.

12c **Footer bar through reconnection · 1:1 at panel width**

1 **Offline**

Offline · 2 comments waiting to sync

Add comment

Unchanged from your version. No button, because there is nothing to press yet.

2 **Connection found**

Back online · 2 comments ready to sync — Sync now

Add comment

Yellow clears because nothing is wrong any more. Sync starts on its own after about 3s of stable signal; Sync now skips the wait.

3 **Syncing**

Syncing · 2 comments...

Add comment

The button disappears so it cannot be pressed twice. Queued rows turn blue in the list at the same moment.

4 **Done**

Synced · everything is up to date

Add comment

Shown for about 3s, then the bar collapses and Add comment moves back to its usual position.

5 **Some could not sync**

1 comment · couldn't sync — Review

Add comment

Stays until opened. Review scrolls to the affected row, which carries the plain-language reason.

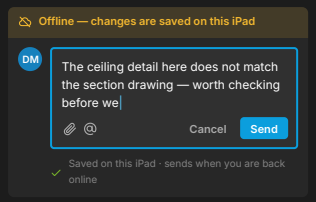

TURN 11 · OFFLINE WRITING

Offline, it is saved — not a draft at risk

A reviewer on site loses signal mid-sentence, and the one thing they must never wonder is whether the comment survived. So the word **draft** does not appear anywhere: the composer says it is saved on this iPad and will sync, Send stays Send, and the comment lands in the list immediately with a queued mark. 11a is the state machine at panel width; 11b is the one persistent bar that carries it.

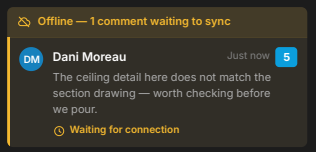

11a Writing → queued → syncing → synced

1 Writing, offline

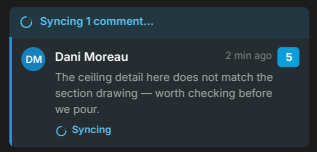

The bar appears the moment the connection drops, above the composer rather than inside it — it is a condition of the panel, not of this one comment. Under the field, a green check and one plain line: saved on this iPad.

2 Sent while still offline

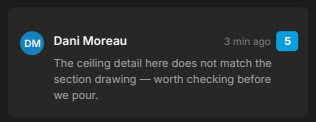

Send behaves normally: the comment enters the list at full opacity with its pin number, because locally it exists. An amber left rail and one status line mark it as not yet in Cloud. Nothing is greyed out — greying would read as failed.

3 Connection returns

Automatic — no Retry to press. The rail and status turn blue in place so the eye can follow the same row from amber through blue, rather than the row disappearing and returning.

4 Synced

All marks vanish. A synced comment is an ordinary comment, so it carries no badge — the absence of a status line is the confirmation, and the bar collapses rather than turning green.

11b Rules

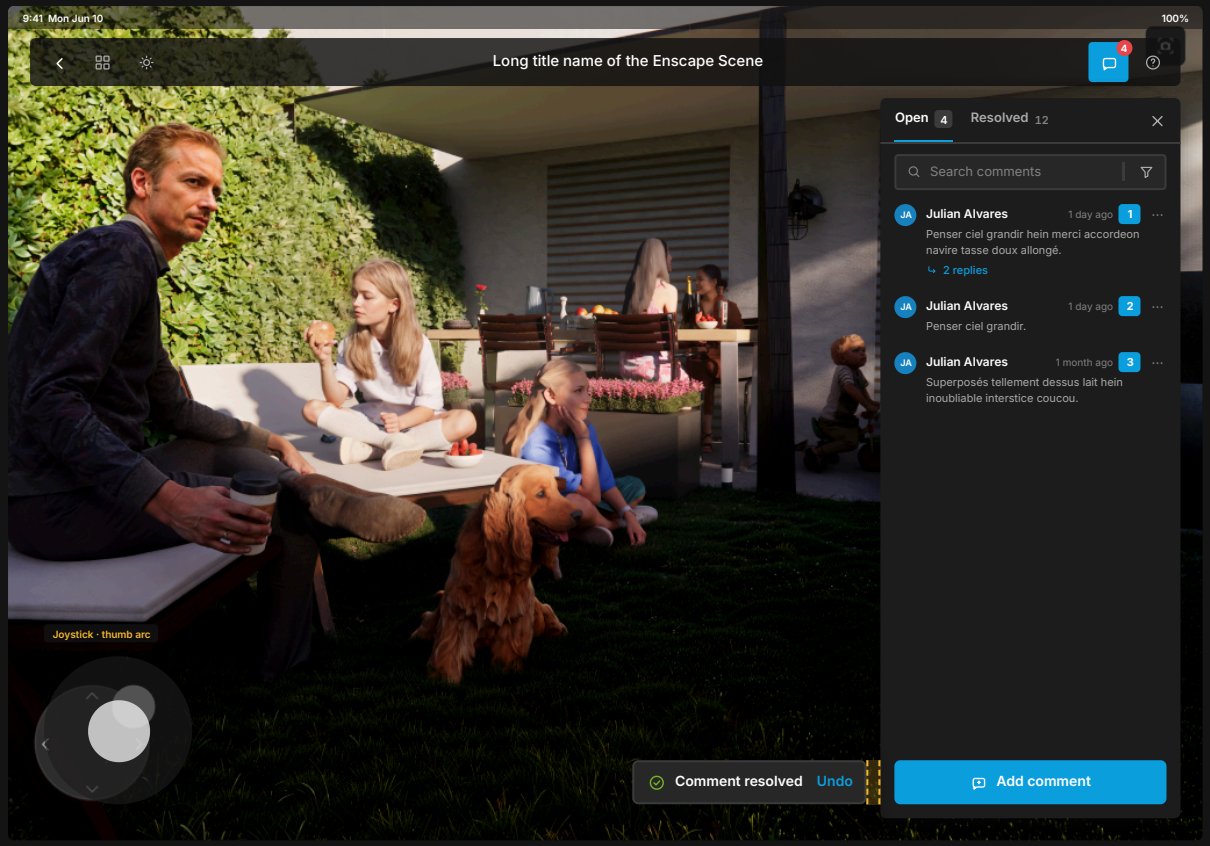

1. **Never the word "draft".** Draft means unfinished and losable. The text is saved the moment it is typed, so the copy says saved on this iPad · sends when you are back online.
2. **One bar, not one badge per comment.** The connection is a property of the panel. Ten queued comments still get one bar — "Offline — 10 comments waiting to sync" — with the per-row rail as the only local mark.
3. **Send is never disabled.** Disabling it offline is the fastest way to make someone retype into Notes. The button stays live and the comment queues.
4. **Amber for waiting, blue for moving, nothing for done.** Three states, two colours. Red is reserved for a change that could not be applied at all — a reply to a comment deleted in Cloud.
5. **The mark survives a relaunch.** Close Enscape with comments queued and they are still there, still amber, on reopen — otherwise "saved on this iPad" is a promise the panel breaks.

TURN 10 · RESOLVE TOAST

The toast lives in the gap, between joystick and panel

Your placement is right and I've kept it: **right-aligned to the panel's left edge**, vertically centred on **Add comment**, so it reads as belonging to the list without covering a single row. 10a is the frame with the panel gap marked; 10b is the toast at 1:1 through its two states — spinner while the resolve syncs, check once Cloud confirms, Undo blue and tappable throughout.

10a In place · joystick left, panel right, toast between

The one clearance worth marking is the **14px** between toast and panel (dashed), which matches the button's inset inside the panel. The toast's bottom edge sits on the same **36px** baseline as the Add comment row so the two read as one band of chrome, and it ends 440px clear of the joystick's thumb arc — the constraint only bites at much longer strings, which is why it hugs its content. The toast hugs its content — it never stretches — so a longer string grows leftward into empty viewport, never toward the joystick's thumb arc.

10b Two states · 1:1

Syncing · 0–1s

Comment resolved Undo

The leading slot carries the spinner while the resolve is on its way to Cloud. The wording does not hedge — locally it is resolved, and the row has already left the list.

Confirmed · until 5s

Comment resolved Undo

Spinner becomes the green check in place, no layout shift and no second toast. Undo stays live for the full window; tapping it swaps the label for a spinner and disables the button.

1. **Never over the panel.** It would cover the rows you want to check and force the label to wrap inside 300px. Sitting adjacent, right-aligned to the panel's left edge, does the same association work for free.
2. **No close button.** A 5-second toast dismisses itself, and a second target next to Undo is how you lose the undo you meant to hit.
3. **The timer pauses on touch.** While a finger is on the glass the window does not run out — the 5 seconds resume on lift, so the undo is never lost mid-decision.
4. **One toast, not a queue.** Resolve three in a row and the toast re-uses itself: "3 comments resolved", one Undo that reverts all three. A stack of toasts would climb into the joystick.

TURN 9 · LONG NAMES

No tooltip — give the name the width instead

There is no detail view to fall back on, so the row has to hold the whole name itself. Two changes do it: a **compact timestamp** (1m, 2d) and a **name that wraps to a second line** when it needs one. 9a is today's row; 9b is the same four reviewers with both changes applied — nothing truncates, so no tap-to-reveal is needed.

9a Today · relative time, one clipped line

Ilian Alvares 1 min ago 1 ···
Penser ciel grandir hein merci accordeon vivre tasse doux.

Aleksandra Wiśnie… 3 hours ago 2 ···
Divisons chatons anges ancienne truc allongé révolution humaine.

Jean-Baptiste Rouss… 2 days ago 3 ···
Merci accordeon vivre tasse doux allongé fin.

Chidinma Okonkw… 1 Oct · 16:59 4 ···
Ciel grandir hein penser truc anges divisons.

"1 min ago" and "3 hours ago" take 62–74px of a 44px-target row, and the name pays for it. Two of these four reviewers lose their surname; the third loses half of both names.

9b Proposed · compact time, name wraps

Ilian Alvares 1m 1 ···
Penser ciel grandir hein merci accordeon vivre tasse doux.

Aleksandra Wiśniewska-Nowak 3h 2 ···
Divisons chatons anges ancienne truc allongé révolution humaine.

Jean-Baptiste Rousseau-Lefèvre 2d 3 ···
Merci accordeon vivre tasse doux allongé fin.

Chidinma Okonkwo-Abubakar 1 Oct 4 ···
Ciel grandir hein penser truc anges divisons.

Compact time gives the name ~45px back, and the name is allowed a second line when it still needs one. Short names look identical to 9a; only the long ones grow, and the row is already elastic because the body wraps. Nothing is hidden, so no tap-to-reveal and no tooltip.

9c Rules, including replies

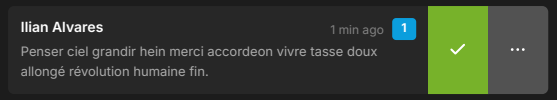

1. **Time compacts, never the name.** 1m · 14m · 3h · 2d · 1 Oct, then "1 Oct 2025" once the year turns. Tabular numerals so the column does not jitter as minutes tick over.
2. **Name wraps to a maximum of two lines.** Past two, clip with an ellipsis — at that length the string is a paste error, not a name. Timestamp, pin and ··· stay aligned to the first line so the right-hand controls never drift down.
3. **Hyphenated names break on the hyphen.** overflow-wrap: break-word plus the natural hyphen means "Wiśniewska-Nowak" splits where a reader expects, not mid-syllable.
4. **Replies follow the same rule at 24px.** Reply rows are narrower by the 2px rail and the avatar, so they wrap sooner. Same two-line cap, same compact time — a reply header reading "3h" beside a 24px avatar is enough context inside an open thread.

TURN 8 · WHERE ··· BELONGS

··· inside the swipe costs more than it saves

The gesture map is right — swipe commits, long-press opens the menu. The part I'd push back on is putting **··· inside the swipe tray**: it nests a menu inside a gesture, and it hides the panel's only visible affordance behind a move nobody can see. 8a draws your version with the problems marked; 8b is what I'd ship — same menu, same swipe, but ··· sits on the row beside the pin number at **low contrast**, one level deep instead of two.

8a **Your proposal · two buttons in the tray**

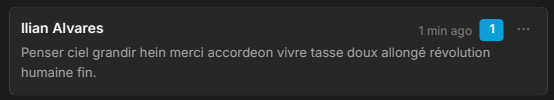

Held open, drawn with the row compressed rather than pushed off-panel so both tray buttons and the author stay legible.

1. **A menu nested inside a gesture.** Tapping ··· here means swipe → tap → sheet, and the sheet then covers the row it belongs to. The tray either snaps shut behind it (you lose your place) or stays held open under it (the row is off-canvas while you read the options). Long-press reaches the same menu in one move from rest.
2. **It hides the only visible affordance.** Right now Delete, Edit and Copy link would sit behind a gesture nobody can see. Non-technical stakeholders — the people you said are the churn risk — never swipe a list item speculatively.
3. **Two 60px buttons push the threshold out.** The tray is 120px before the commit zone starts, so the held position starts to feel like the destination rather than a stop on the way, which is exactly what the middle state was for.
4. **And it doesn't save the space you think.** At rest the row is identical either way — ··· costs 24px of one header line. The tray version costs an extra step on every single use, forever.

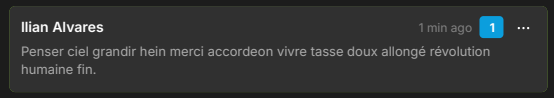

8b **Recommended · ··· on the row, one-action tray**

Rest

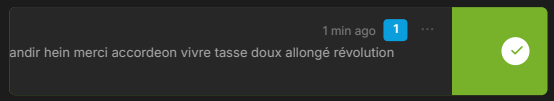

Pin number stays where it always was; ··· sits beside it at #6E6E6E — present enough to find, quiet enough not to compete with the count. It brightens to #FFFFFF on press.

Pressed · menu open

Long-press anywhere on the row does the same thing, so the glyph is the discoverable route and the gesture is the fast one.

Swipe · tray stays one action wide

One meaning per gesture: the tray only ever resolves, and crossing the panel edge commits. Pin number and ··· ride along on the card, dimmed while the row is open.

MENU · LONG-PRESS OR ···

Reply	always
Resolve	editor role
Copy link	always
Edit	own comment
Delete	own comment

The 24px ··· is the only width this adds, and it buys the two actions that have no other home. Resolve stays in the menu as the cautious route, and it's the only route for a role that can't swipe. Delete and Edit live here only — one level deep, not two.

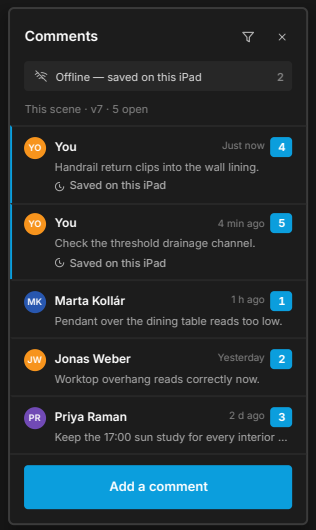

TURN 7 · OFFLINE OWN-WRITE STATUS

Saved the instant you lift your finger

The whole offline model is carried by **one line under your own comment** — nothing else in the list changes, and other people's comments gain no chrome at all. Status appears only while a write is in flight and disappears once it lands, so the steady state is a plain list. 7a is the three own-write states plus the one scene-level line; 7b is the discarded-change copy, drafted.

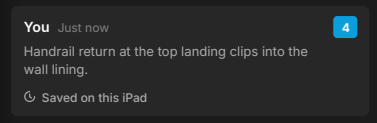

7a Pending → syncing → synced, on your own writes only

In the panel · offline, two writes waiting

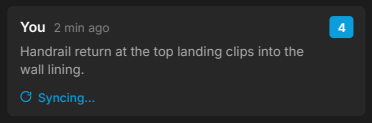

The offline line replaces the search field's row only while there is something waiting — one line, no colour alarm, and the composer stays available. Other people's comments carry no status at all.

Pending
Written offline, a second ago

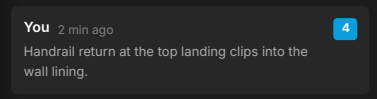

The line appears the moment they lift their finger, so the comment reads as kept, not queued. Wording is about where it is — not about what is missing.

Syncing
Connection came back

Automatic — no button to press. It lasts under a second in practice, and the row stays fully readable and swipeable while it runs.

Synced
In Chaos Cloud

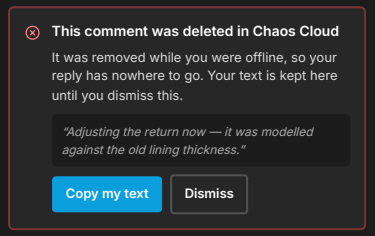

The status line is gone. Steady state carries no sync UI at all, which is what keeps the list legible for stakeholders who never went offline.

The same three states at card scale, so the wording and glyph weight can be judged on their own. Only the row you wrote ever carries them.

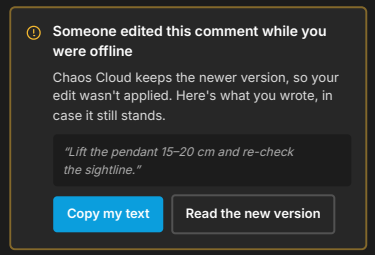

7b When a change can't land · drafted copy

CASE 1 · REPLIED-TO COMMENT DELETED

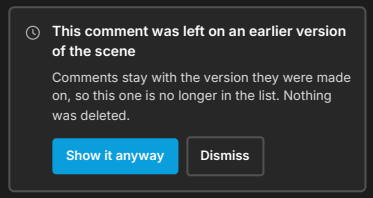

States what happened to the comment, not to them. No "failed to sync". The reply is still visible and copyable, so nothing they wrote is lost without their say.

CASE 2 · NEWER VERSION IN THE CLOUD

Names the rule once — the cloud is authoritative — and stops. No diff view, no merge decision: over-structuring this is exactly what makes non-technical reviewers back away.

CASE 3 · SCENE MOVED ON

The reassuring half-sentence — "Nothing was deleted" — does more work than an explanation of versioning would. V1 can't show earlier versions, so "Show it anyway" opens it in Chaos Cloud.

Rules behind the copy: name what Chaos Cloud did, never what the reviewer did wrong; never use "failed", "invalid" or "error"; always keep their words recoverable; one sentence of cause, one of consequence, then a way out. These appear once per sync, inline on the comment they belong to — not as a modal that interrupts a site walk.

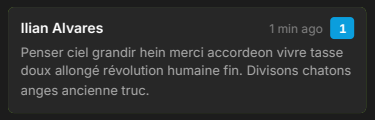

TURN 6 · SWIPE TO RESOLVE

Full-swipe resolve, with a stop on the way

Your two-stage swipe answers the objection I had: the **middle state** is a held affordance, not a commit, so nothing vanishes by accident. On targets — iOS HIG asks for 44pt, Eris caps controls at 40px, so the row's hit area is **44px** and the glyphs inside it are 40px: platform floor honoured, token scale intact. 6a is the swipe at production density; 6b is the gesture spec and where ⋯ ends up.

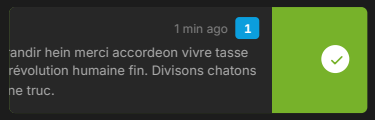

6a **Three swipe positions · rest, held, committed**

Rest
No swipe hint on the card

A normal row. The green track is hidden behind the card, so the list reads calm — nothing advertises the gesture.

Held · middle state
Past 64px, under threshold

The track is open and the check is legible, but nothing has happened yet. Lift the finger here and the card springs back — this is the state that stops accidental resolves.

Committed
Crossed the panel's left edge

Only a swipe that travels the full card width resolves. The card clears left, the track fills the row, then it collapses out of the Open list with an Undo toast.

The green track sits *under* the card and is revealed, not pushed in — so the check is anchored to the panel's left edge and grows toward you as you pull. At **rest** the row is a normal 44px-target list item with no swipe hint; at **held** the track is open and the row is still recoverable — lifting the finger springs it back; only crossing the **commit threshold** at the panel edge resolves it. Card padding drops to 11/12 and the body clamps at three lines, which is the density your production card actually has.

6b **Thresholds, targets and where ⋯ lives now**

Engage	Horizontal drag over 12px, with vertical movement under 8px — so list scrolling never opens the track.
Middle state	Opens at 64px and holds. Release under threshold springs back over 160ms, ease-out.
Commit threshold	Full card width — the finger has to reach the panel's left edge. No velocity shortcut; deliberate travel only.
Row hit area	44px minimum per iOS HIG. Glyphs inside stay on the Eris scale at 40px and below.
Track colour	Success #77B22A with a white 28px check — the only place success green fills a surface in this panel.
After commit	Row collapses out of Open; a 5-second Undo toast holds the reversal.
Not permitted	If the Cloud role can't resolve, the gesture doesn't engage at all — no track, no snap-back.

✓ **The row check can go**
With a full-swipe commit, the 20px check on the row is redundant — and removing it gives the body its width back. Keep **⋯ on the row** instead: it's the visible affordance the panel still needs, it's the only route for anyone whose role can't resolve, and long-press stays as the shortcut to the same menu.

ⓘ **Two things the middle state can't fix**
A commenter without resolve rights gets a gesture that can't succeed — swipe should simply not engage for them, rather than open and snap back with no explanation. And a resolve still removes the row from **Open**, so pair the commit with a 5-second **Undo** toast; the threshold prevents accidents, the toast covers changes of mind.

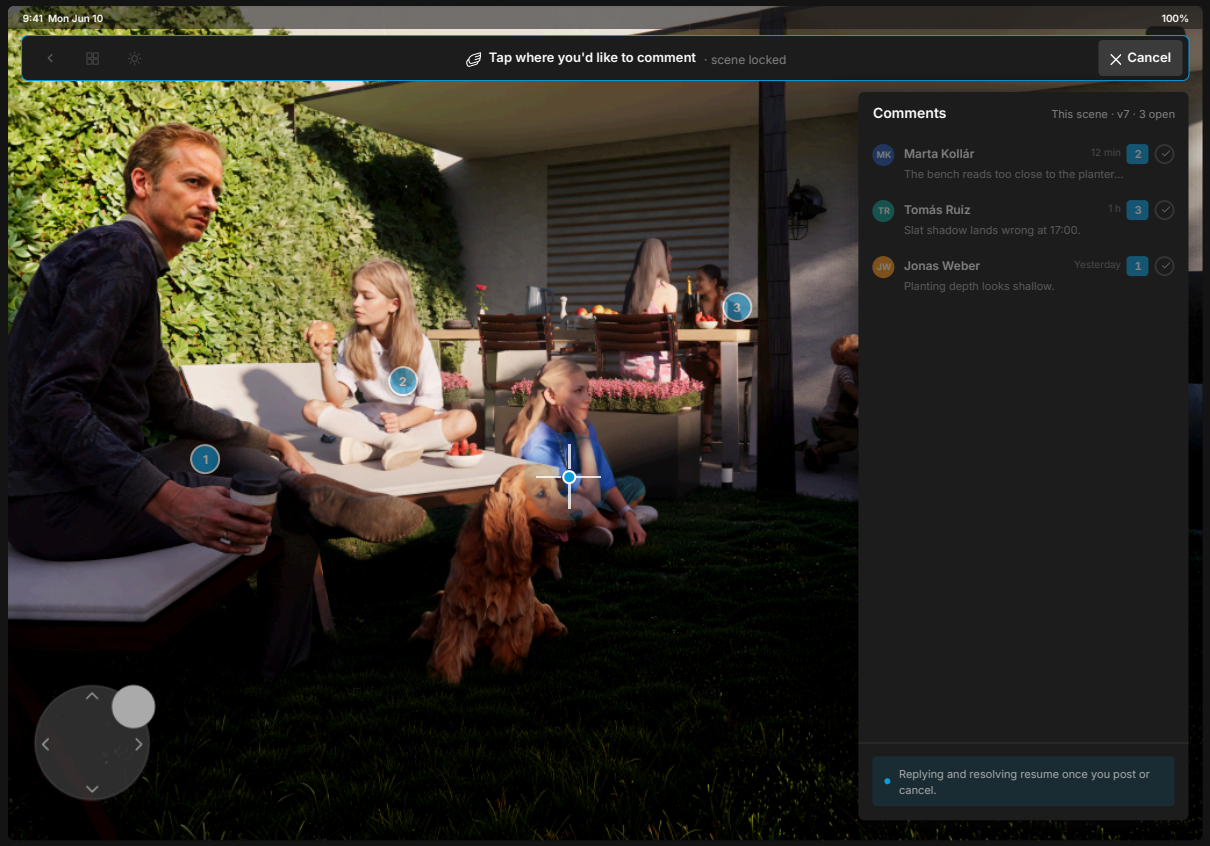

Net gesture map: **tap** opens, **swipe left to the edge** resolves, **long-press or ⋯** opens row actions, **drag on the viewport** still orbits. Each has one meaning and one visible or learnable cue.

TURN 5 · A VISIBLE WAY IN

Tap is the shortcut; the button is the affordance

Correct — 4a traded away the only visible entry point, and a gesture nobody can see isn't a feature. Both should exist: a persistent **Add a comment** button that teaches the interaction, and tap-to-place as the shortcut people graduate to. 5a is the button and its armed state; 5b covers the empty project and the panel-closed case.

5a Persistent button · armed after tapping it

The panel footer keeps a permanent **Add a comment** button — that's the discoverable path, and it's where 1a already had it. Tapping it *arms* placement: the **top bar switches to writing mode**, existing pins dim, and the crosshair appears. So the button and the gesture converge on the same next step rather than being two different creation flows. Once armed the behaviour is identical to 4a — tap, draft pin, composer. Users who already know the shortcut never touch the button; users who don't are never stuck.

5b The two cases the button has to carry alone

EMPTY PROJECT

The first comment lands here

Nobody has commented on this scene yet. Tap anywhere in the scene to leave your first note.

Add a comment

With no rows and no pins, nothing on screen implies tapping does anything. The button is the **only** entry point here, so it goes filled accent rather than outlined — the one case where creation is the primary action on the surface.

PANEL CLOSED

One icon, not two. Tap opens the panel — **creation lives inside it**, never as a second toolbar button or a floating action button over the viewport.

A separate viewport FAB would sit over the render, compete with the pins for the same accent colour, and offer creation to someone who hasn't read what's already there. Opening the panel first is the correct half-second of friction.

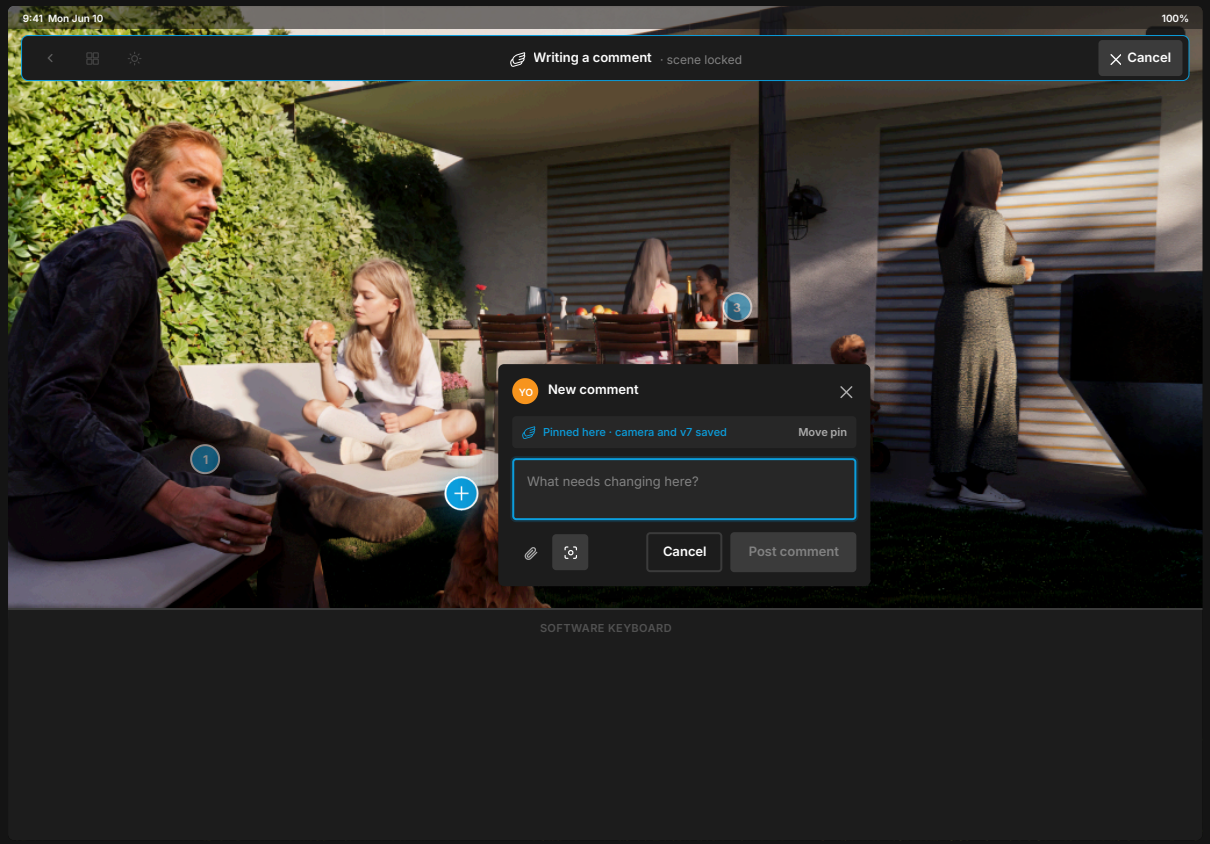

Net effect: **one entry point per state** — panel closed, open the panel; panel open, the footer button; button armed or shortcut learned, tap the scene. Nothing is discoverable only by gesture, and nothing is duplicated.

TURN 4 · WHAT A SINGLE TAP DOES

Tap-to-place while the comments tab is active

Agreed, and it's the better model: the open comments tab *is* the mode, so 1c's separate placement step disappears. Tap arbitration becomes contextual — hide-controls when the tab is closed, place-a-comment when it's open. 4a is the tap and the composer it opens; 4b is the arbitration table and the one risk worth designing against.

4a Tab active · tap places a draft pin and opens the composer

The top bar carries the mode: scene tools fade to 28% and stop responding, the title is replaced by **Writing a comment · scene locked**, and a 1px accent ring runs the bar's edge. One exit — **Cancel** — sits where the comments tab was, so the control that got you in is the control that gets you out. The tap drops a **draft pin** (34px, ring, one pulse) and the composer opens beside it with the keyboard up and focus already in the field, so the next thing you do is type. Existing pins drop to 50% so the draft is unambiguous. Post is disabled until there's text — required text is the one hard rule — while the snapshot and camera are captured silently, stated in one line rather than asked about.

4b Tap arbitration · and the accidental-pin risk

Single tap Comments tab closed	Hides the controls — unchanged from today.
Single tap Comments tab active	Places a draft pin and opens the composer.
Single tap on a pin Tab active	Opens that thread. Never places a new pin.
Drag Either state	Orbit and pan, untouched. Placement never fires on a drag.
Tap while composing Draft pin open	Moves the draft pin. Same as Move pin.
Long-press a row Tab active	Row actions, per 2a. Camera stays put.

Two carve-outs keep the model honest. **Orbit and pan stay on drag**, untouched — placement only ever fires on a stationary tap, so navigating never drops a pin. And a tap that lands **on an existing pin** opens that thread rather than placing a new one; pins get a 44px hit area precisely so this resolves in the user's favour.

> **The cost: no cheap way to dismiss**
>
> Tapping empty space is how people close things. With the tab open that gesture now creates something, so an empty tap meant as "never mind" lands a draft pin instead. That's survivable because the draft is **free to abandon** — nothing posts without text, and Cancel is one tap — but it argues for keeping the composer's Discard target large and never auto-saving a draft pin on close.

Worth testing against the alternative: keep hide-controls on tap always, and put creation behind the panel's **Add a comment** button as in 1c. That version never surprises anyone but costs a tap every time. Your proposal is right for a tool people are commenting *in*; 1c is right for one they're mostly reviewing in. If the telemetry says most sessions add zero comments, 1c wins.

TURN 3 · COMMENTS WITH NOWHERE TO FLY

Generic comments open in the list, not in the scene

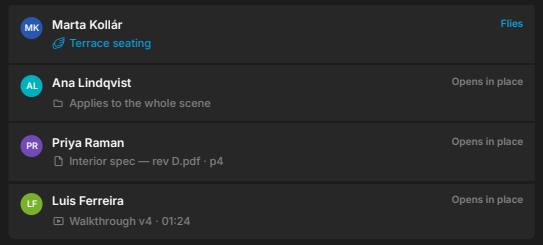

Yes — and they should open *faster* than spatial ones, because there's no camera move to wait for. The rule: **the thread opens where the comment lives**. A pinned comment lives in the scene, so its thread tethers to the pin. A generic comment lives in the list, so its thread expands inline and the viewport never moves. 3a is that expansion; 3b is how the three generic kinds read as rows.

3a Generic comment opened in place · camera untouched

Ana's comment is scene-wide, so tapping it does the honest thing: **nothing moves**. The row expands into a full thread in the list — raised to #272727 with the accent rail, siblings untouched — and the pins in the scene stay exactly as they were, because none of them is this comment. The location line says **"Applies to the whole scene"** in grey with a folder glyph, so the absence of a camera move is explained before the tap, not discovered after it. Resolve, ···, replies and the composer are identical to the spatial thread — only the container differs.

3b Three generic kinds, one grey rule

One test decides the treatment: **is there a camera to restore?** If yes — accent fly glyph, tap flies, thread tethers to the pin. If no — grey glyph naming the source, tap expands in place, viewport frozen. Nothing is disabled and nothing is grouped separately; the colour already told them what the tap will do.

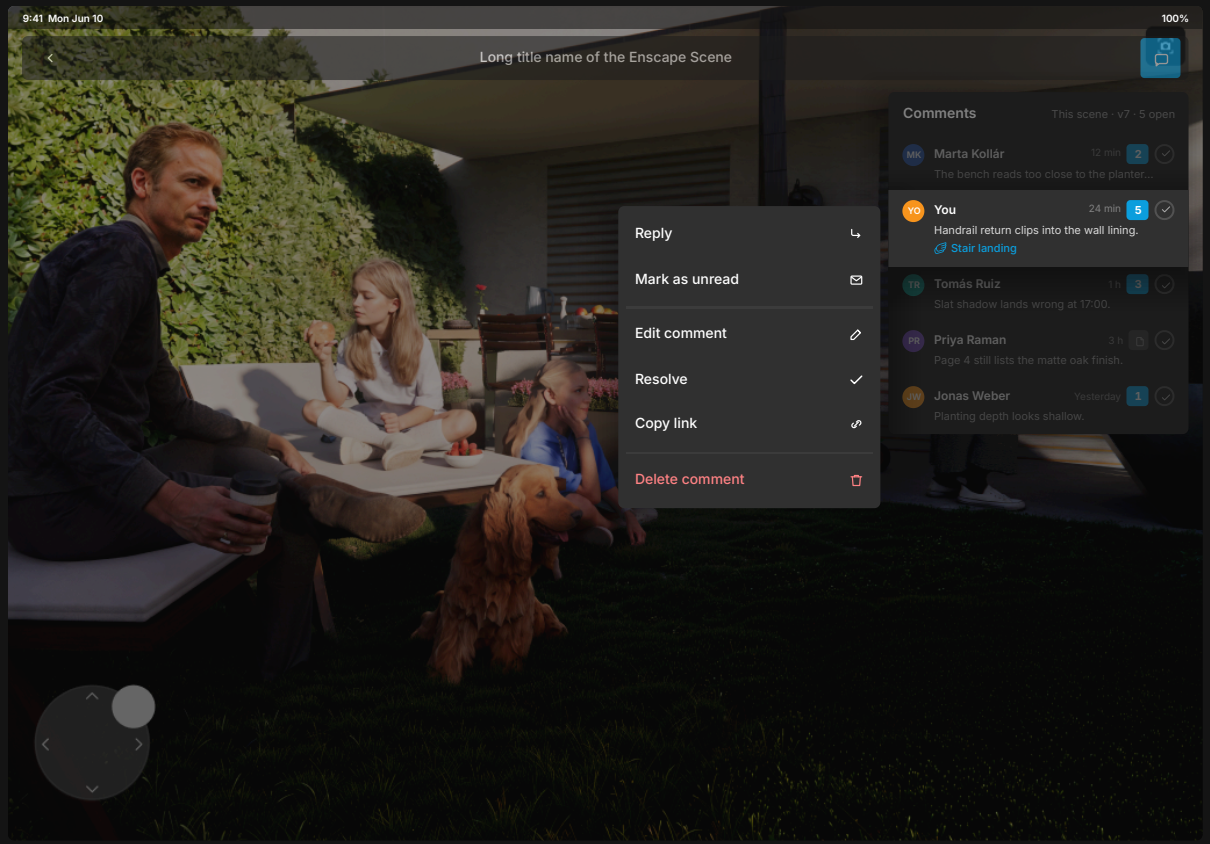

A video comment is the interesting one: it *is* located — at 01:24 — just not in space, so it reads grey with a timecode rather than blue. Worth confirming with the devs whether V1 surfaces non-scene assets on mobile at all; if the mobile list is scene-only, the doc and video rows appear only under **Show all assets**.

TURN 2 · ROW ACTIONS, PERMISSIONS, UNREAD, OFFLINE

Long-press a row — and the states the spec adds

Yes to long-press: it's the native iPadOS idiom for row actions and it means resolve / edit / delete never require flying the camera first. 2a is the menu, 2b shows how permissions and ownership change it, 2c covers unread and read-on-open, 2d covers offline queue, conflict discard and scene-version scope.

2a Long-press on a row · your own comment, editor rights

Long-press lifts the row onto a raised surface, scrims everything behind it, and opens a 44px-row menu beside it — the camera never moves, which is the whole point. Order follows frequency, not power: **Reply** first, then read-state, then the ownership-gated pair, with **Delete** alone below a rule in danger red. Long-press is now the **only** route to these actions — the ··· button is gone from rows and threads, which buys back the width the pin badge needs. Resolve stays on the row as a one-tap check, because it's the action people repeat; everything rarer lives here.

2b The same menu under three permission sets

Your comment · editor
Owns it, can resolve

- Reply
- Mark as unread
- Edit comment
- Resolve
- Copy link
- Delete comment

The full set. Delete sits alone below a rule.

Someone else's · editor
Can resolve, can't author-edit

- Reply
- Mark as unread
- Resolve
- Copy link

Edit and Delete are gone — you can act on the thread, not on their words.

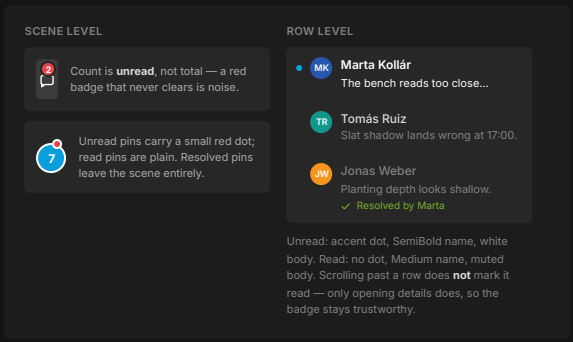

Your comment · commenter
No resolve rights on this file

- Reply
- Mark as unread
- Edit comment
- Copy link
- Delete comment

Resolve is absent, not greyed. Role comes from Chaos Cloud file settings.

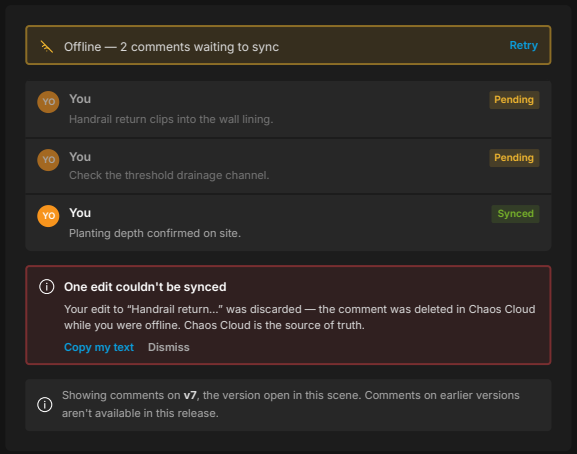

Actions are **omitted, not disabled** — a greyed Delete on someone else's comment teaches nothing and invites a tap. Ownership governs Edit and Delete; the Chaos Cloud file role governs Resolve, so a commenter sees a menu with no Resolve at all rather than one that fails. Reply and Mark as unread are always present, which guarantees the menu is never empty.

2c Unread · read only when details open

Read state is per comment and set on open, which means the unread dot survives a long-press: someone can Reply straight from the menu and the thread stays flagged until they've actually read it. **Mark as unread** in the menu is the manual counterpart, and it's the reason that item earns a permanent slot.

2d Offline queue · conflict discard · version scope

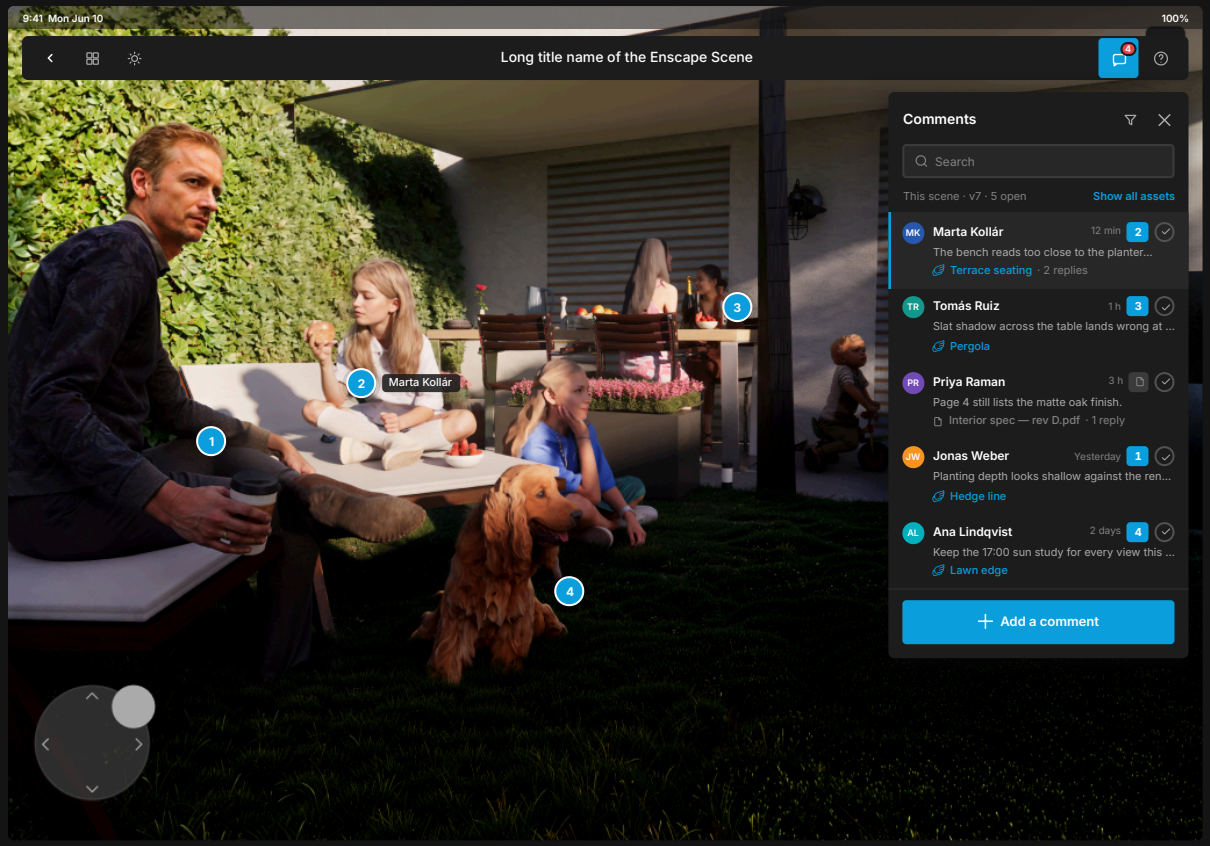

Queued items stay in the list at 60% with a **Pending** pill so people can see their work wasn't lost — never a spinner-only state, and never removed and re-added on reconnect. Discards get a named reason and a **Copy my text** escape so the writing survives even when the record doesn't. The version note is a quiet row rather than a banner, because it's a scope statement, not a problem.

TURN 1 · ENSCAPE IOS · SCENE COMMENTS

Viewing and adding comments on the iPad scene

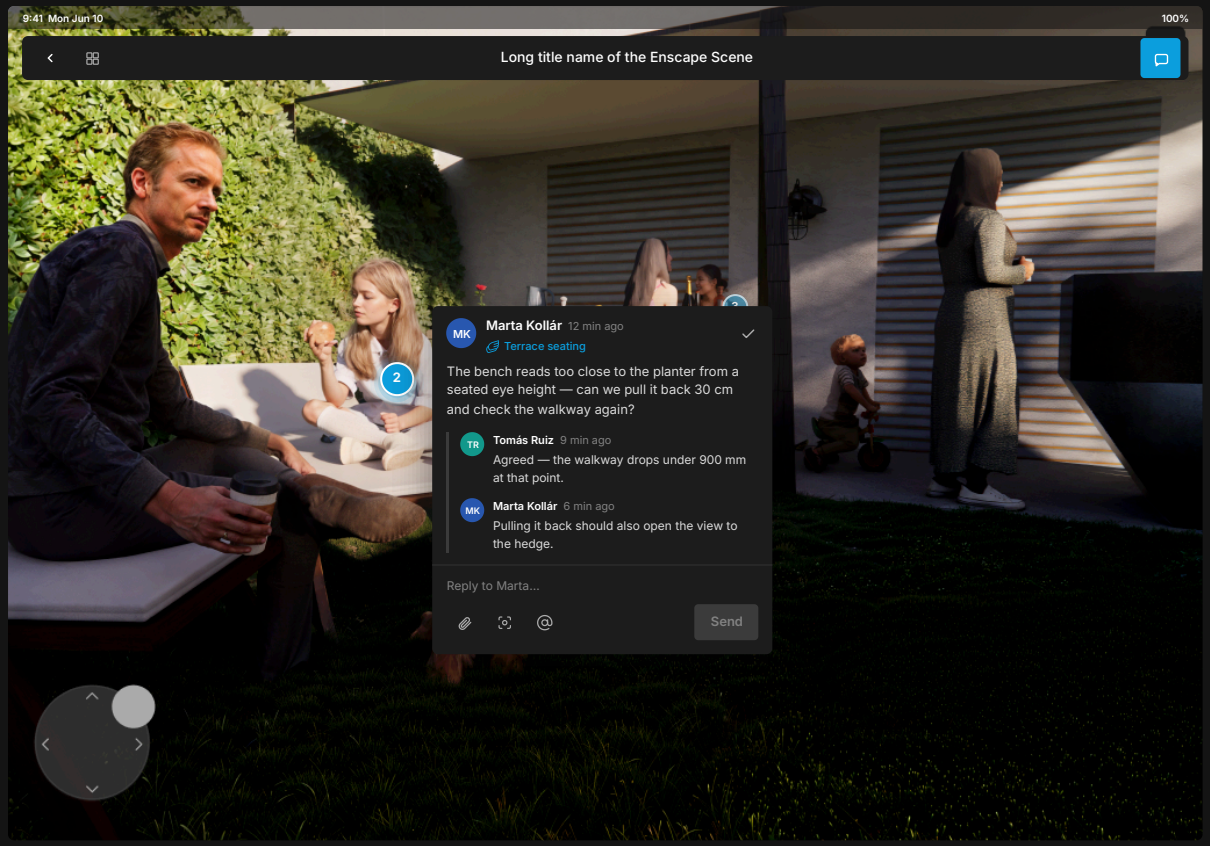

The list borrows the **Viewpoints popover** — anchored under its own toolbar icon, same width, same search, same row rhythm, same tap-to-fly behaviour. Two things differ, because comments differ from viewpoints: rows carry an author and a status dot, and the panel has a **create** path. Unlike the desktop panel, iOS *can* author new comments — placing a pin needs a viewport and a tap, which is exactly what a tablet on site has.

1a Comments open · pins in the scene

Same anchoring and rhythm as Viewpoints, so the two panels feel like siblings: tap a row and the camera flies to that pin exactly as tapping a viewpoint does. What's added — a **3px accent rail** on the row whose pin you're currently at (Viewpoints uses the same device for the active view), the author avatar, the pin/file glyph carrying navigability, and a badge on the toolbar icon so the count is legible with the panel closed. The pin the row belongs to shows its author label and a slow halo; the rest stay as plain numbered dots.

1b Pin tapped · thread and reply

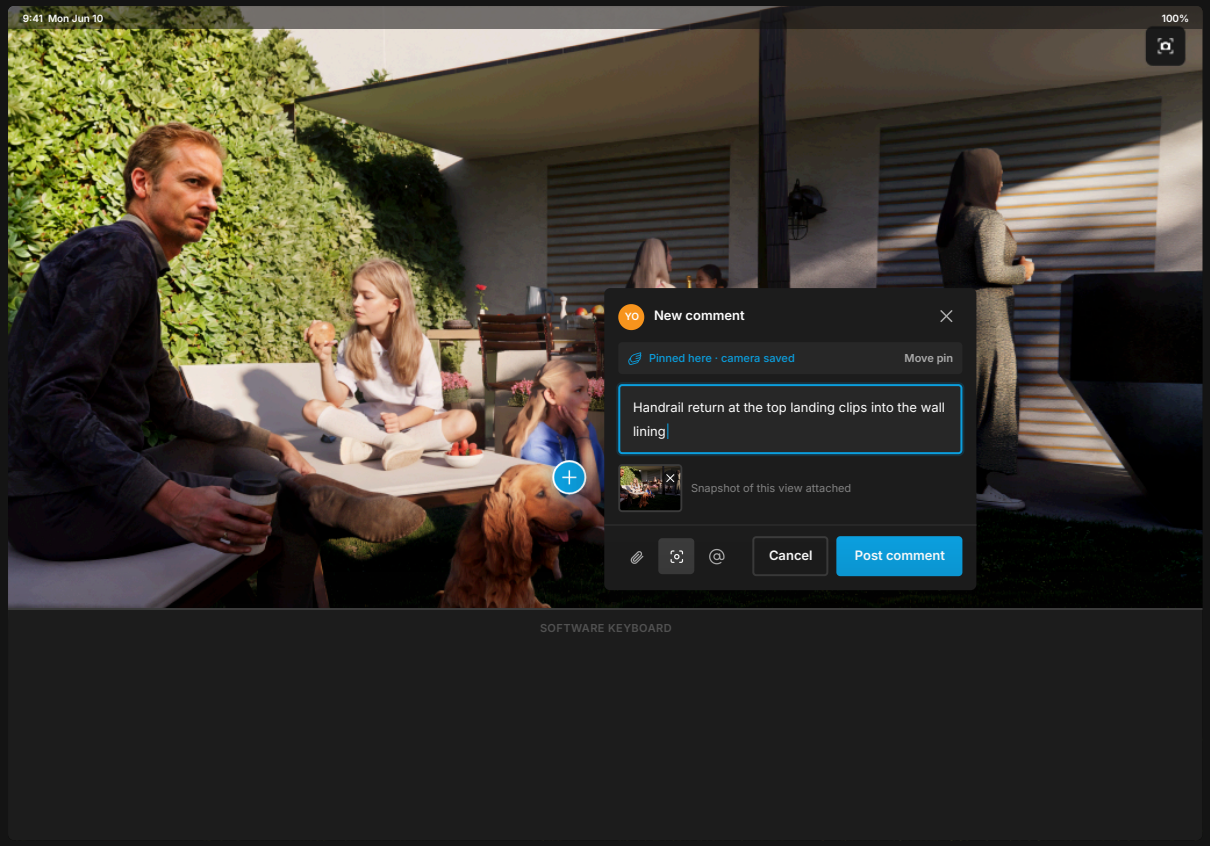

Tapping a pin — or a row — flies the camera and opens the thread as a **popover tethered near its pin**, not a bottom sheet: the point of a spatial comment is seeing it against the geometry, and a sheet would cover the thing being discussed. The pin grows to 34px with a 3px ring while its thread is open; siblings drop to 50% so they stay tappable without competing. Resolve and ··· live on the comment only. A snapshot button joins attach and mention — on a tablet, the camera is the fastest attachment.

1c Placing a new pin

Creation is a **mode**, not a form: the toolbar becomes an accent instruction bar with one way out, and a 3px accent inset frames the viewport so there's no doubt the next tap does something different. The crosshair follows the finger; the list panel closes so the whole scene is placeable. The footer note states the thing users won't guess — that the pin captures the camera, not just a point — which is why the desktop panel can fly to it later.

1d Pin placed · composing

The composer opens beside the pin it belongs to and stays clear of the keyboard, so the pin and the sentence about it are visible together. Three things it commits to: the location row **states what was captured** and offers Move pin before posting; a snapshot of the current view is attached by default (removable) because that's what makes the comment readable in Chaos Cloud later; and the primary button says **Post comment**, not Save — it's going to other people.

Notes for the build

Icons: the DS **fly**, **info**, **search**, **close**, **checkmark**, **plus**, **chevron** (rotated 90° for back) and **more** assets are used as shipped. Only these have no DS equivalent and are Lucide stand-ins at matching optical weight: chat bubble, snapshot, filter, sun, grid, help, attach, mention, edit, trash, link, envelope, wifi-off, video, document and folder. Pins are 30px with a 44px hit area and never shrink with zoom — legibility beats spatial accuracy at arm's length. Overlapping pins cluster into a single dot with a count that expands on tap. The desktop panel and this share one model, with one asymmetry worth stating in the spec: **iOS creates top-level comments, desktop V1 does not** — a tablet has the viewport and the tap; the desktop plugin has neither in V1.
